ABSTRACT

Background

Influenza vaccination of elderly individuals is recommended worldwide and has been targeted toward the elderly and those at serious risk of complications.

Objectives

Our aim was to review the evidence of efficacy, effectiveness and safety of influenza vaccines in individuals aged 65 years or older.

Search strategy

We searched the Cochrane Central Register of Controlled Trials (CENTRAL), which contains the Cochrane Acute Respiratory Infection (ARI) Group's specialized register, the Cochrane Database of Systematic Reviews, and the Database of Abstracts of Reviews of Effectiveness, (2006, issue 1); MEDLINE (January 1966 to March Week 3 2006); EMBASE (Dialog 1974 to 1979; SilverPlatter 1980 to December 2005); Biological Abstracts (SilverPlatter 1969 to December 2004); and Science Citation Index (Web of Science 1974 to December 2004).

Selection criteria

We considered randomised, quasi-randomised, cohort and case-control studies assessing efficacy against influenza (laboratory-confirmed cases) or effectiveness against influenza-like illness (ILI) or safety. Any influenza vaccine given independently, in any dose, preparation or time schedule, compared with placebo or with no intervention was considered.

Data collection and analysis

We grouped reports first according to the setting of the study (community or long-term care facilities) and then by level of viral circulation and vaccine matching. We further stratified by co-administration of pneumococcal polysaccharide vaccine (PPV) and by different types of influenza vaccines. We analysed the following outcomes: influenza, influenza-like illness, hospital admissions, complications and deaths.

Main results

Sixty-four studies were included in the efficacy / effectiveness assessment, resulting in 96 data sets. In homes for elderly individuals (with good vaccine match and high viral circulation) the effectiveness of vaccines against ILI was 23% (6% to 36%) and non-significant against influenza (RR 1.04: 95% CI 0.43 to 2.51). We found no correlation between vaccine coverage and ILI attack rate. Well matched vaccines prevented pneumonia (VE 46%; 30% to 58%), hospital admission (VE 45%; 16% to 64%) and deaths from influenza or pneumonia (VE 42%, 17% to 59%). In elderly individuals living in the community, vaccines were not significantly effective against influenza (RR 0.19; 95% CI 0.02 to 2.01), ILI (RR 1.05: 95% CI 0.58 to 1.89), or pneumonia (RR 0.88; 95% CI 0.64 to 1.20). Well matched vaccines prevented hospital admission for influenza and pneumonia (VE 26%; 12% to 38%) and all-cause mortality (VE 42%; 24% to 55%). After adjustment for confounders, vaccine performance was improved for admissions to hospital for influenza or pneumonia (VE* 27%; 21% to 33%), respiratory diseases (VE* 22%; 15% to 28%) and cardiac disease (VE* 24%; 18% to 30%); and for all-cause mortality (VE* 47%; 39% to 54%). The public health safety profiles of the vaccines appear to be acceptable.

Authors' conclusions

In long-term care facilities, where vaccination is most effective against complications, the aims of the vaccination campaign are fulfilled, at least in part. However, according to reliable evidence the usefulness of vaccines in the community is modest. The apparent high effectiveness of the vaccines in preventing death from all causes may reflect a baseline imbalance in health status and other systematic differences in the two groups of participants.

PLAIN LANGUAGE SUMMARY

The review looked at whether vaccines prevented seasonal influenza and its complications in people aged 65 or older

Influenza vaccination of elderly individuals is recommended worldwide as people aged 65 and older are at highest risk for complications, hospitalisations and deaths from influenza.

The review looked at evidence from experimental and non-experimental studies carried out over 40 years of influenza vaccination. Seventy-one studies were included and were grouped first according to study design and then to setting (community or long-term care facilities). The results of the review are mostly based on non-experimental (observational) studies, which are at greater risk of bias, as not many good quality trials were available. Trivalent inactivated are the most commonly used influenza vaccines. Best effectiveness of current vaccines in preventing clinical illness and its complications was seen in long-term care facilities (for example nursing homes) where vaccines prevented about 45% of pneumonia cases, hospital admissions and influenza-related deaths. This compared to about 25% vaccine efficacy in preventing hospitalisation from influenza or respiratory illness in open community settings. The public health safety profile of the vaccines appears to be acceptable.

BACKGROUND

Vaccines have been the main global weapon to minimise the impact of influenza in the elderly for the last four decades. In the year 2000, 40 out of 51 developed or rapidly developing countries recommended vaccination for all persons aged 60 or 65 or older (van Essen 2003). Up to 290 million doses of vaccine were distributed worldwide in 2003 (WHO 2005). According to the Centres for Disease Control (CDC), the primary goal of influenza vaccination in the elderly is to reduce the risk of complications among persons who are most vulnerable (ACIP 2005; CDC 2004). To achieve this goal, CDC defined two higher priority groups: adults aged 65 years or older and residents of nursing homes and long-term care facilities. Currently there is no up-to-date comprehensive assessment of the effects of influenza vaccines in the elderly. Of the two existing systematic reviews looking at the effects of influenza vaccines in the elderly, one is now over a decade old and its conclusions may be affected by the lack of inclusion of recent evidence (Gross 1995). The other review has several methodological weaknesses which may affect the authors' conclusions (for example, the exclusion of studies with denominators smaller than 30 and pooling of studies using different designs). This review also includes a limited number of studies (Vu 2002). An accurate assessment of the effects (efficacy, effectiveness and safety profile) of influenza vaccines is essential to allow rational choice between alternative strategies.

OBJECTIVES

To identify and appraise all the comparative studies evaluating the effects of influenza vaccines in the elderly (aged 65 years and older), irrespective of setting.

To assess the effectiveness of vaccines in preventing influenza, ILI, hospital admissions, complications and mortality in the elderly.

To document the types and frequency of adverse effects associated with influenza vaccines in the elderly.

METHODS

Criteria for considering studies for this review

Types of studies

We considered randomised, quasi-randomised, cohort and casecontrol studies. For study design definitions see Appendix 1. To assess rare adverse effects we also looked for surveillance studies. Despite being non comparative, they provide information about rare and severe events possibly related to influenza vaccines.

Types of participants

Elderly participants aged 65 years or more, irrespective of settings. Studies which assessed efficacy in selected groups affected by a specific chronic pathology (i.e. diabetes or cardiac disease) were excluded as we were interested in the whole population. The question of whether these vaccines are effective in specific at risk populations is the topic of other reviews.

Types of interventions

Vaccination with any influenza vaccine given independently, in any dose, preparation or time schedule, compared with placebo, or with no intervention.

New as yet unlicensed types of vaccines were also considered (for example, live attenuated and DNA vaccines).

Vaccination of staff in order to protect patients and residents admitted into hospitals, nursing homes and long-term care facilities has been assessed by a separate review (Thomas 2005).

Studies in which vaccine was administered after the beginning of the epidemic period were excluded.

Vaccines for preventing influenza in the elderly (Review)

Old oil adjuvant vaccine or vaccines with a content greater than 15 μ g of hemagglutinin / strain / dose were excluded from the safety assessment.

Types of outcome measures

Primary outcome measures for treatment efficacy and effectiveness

Outcomes occurring within the epidemic period (the six month winter period, if not better specified) were included. When authors presented data according to different levels of viral circulation, data restricted to higher viral circulation only were included.

- 1. Cases of influenza clinically defined from a list of likely respiratory and systemic signs and symptoms. We accepted the trial authors' definition of clinical illness because some states have their own official definition.
- 2. Cases of influenza laboratory confirmed (by means of viral isolation and/or serological supporting evidence).
- 3. Cases of influenza (as defined above) admitted to hospital.
- 4. Deaths (total).
- 5. Deaths due to influenza (as defined above) or to its complications.
- Other direct or indirect indicator of disease impact: pneumonia; hospitalisation due to any respiratory disease, hospitalisation due to heart disease.

Studies with generic outcomes (deaths from all causes, for example) and long-term (one year) follow up were excluded as most illnesses were most likely due to causes other than influenza.

Studies reporting only serological outcomes were excluded.

Outcome measures for adverse events

- 1. Local events for aerosol vaccines (upper respiratory tract infection symptoms such as cough, coryza, sore throat, hoarseness, within seven days of vaccination.
- 2. Local events for parenteral vaccines (tenderness/soreness, erythema, induration, arm stiffness) within seven days from vaccination.
- 3. Systemic events (myalgia, fever, headache, fatigue, indisposition, rash, angioedema, asthma) within seven days from vaccination.
- 4. Rare events (thrombocytopenia, neurological disorders, Guillan Barrè Syndrome (GBS)).

Search methods for identification of studies

We searched the Cochrane Central Register of Controlled Trials (CENTRAL), which contains the Cochrane Acute Respiratory Infection (ARI) Group's specialized register, the Cochrane Database of Systematic Reviews, and the Database of Abstracts of Reviews of Effectiveness, (2006, issue 1); MEDLINE (January 1966 to March Week 3 2006); EMBASE (Dialog 1974 to 1979; Silver-Platter 1980 to December 2005); Biological Abstracts (SilverPlatter 1969 to December 2004); and Science Citation Index (Web of Science 1974 to December 2004).

The following MEDLINE search terms were combined with a methodological search filter for high sensitivity in identifying randomised controlled trials in MEDLINE (Dickersin 1994) and adapted to search the other above mentioned electronic databases. **MEDLINE (OVID)**

There were no language or publication restrictions. The search of CENTRAL included trial reports identified by the systematic search by hand of the journal *Vaccine*.

In order to identify additional published and unpublished studies: - the Science Citation Index was used to identify articles that cite the relevant studies;

- the relevant studies were also keyed into PubMed and the Related Articles feature used;

- bibliographies of all relevant articles obtained, any published review and proceedings from relevant conferences were assessed for additional studies;

- Internet sources were also explored: NHS National Research Register (http://www.update-software.com/national/) ; the Meta-register of Clinical Trials (http://www.controlled-trials.com/) the digital dissertations website (http://wwwlib.umi.com/dissertations);

- the Vaccine Adverse Event Reporting System website was searched (http://www.vaers.org);

- first or corresponding authors of relevant studies was contacted to identify further published or unpublished trials;

- vaccine manufacturers listed at the WHO web site were also contacted.

Data collection and analysis

Inclusion procedure

Two review authors (TOJ and DR) independently applied inclusion criteria to all identified and retrieved articles.

Assessment of methodological quality

Experimental studies

The review authors independently assessed the methodological quality of the included studies using criteria from the Cochrane Reviewers' Handbook (Deeks 2004) and results were introduced into the sensitivity analysis.

Studies were classified according to the following criteria: Randomisation:

A = individual participants allocated to vaccine or control group. B = groups of participants allocated to vaccine or control group.

Generation of the allocation sequence:

A = adequate, for example, table of random numbers or computer generated random numbers.

B = inadequate, for example, alternation, date of birth, day of the week, or case record number.

C = not described.

Allocation concealment:

A = adequate - for example, numbered or coded identical containers administered sequentially, on-site computer system that can only be accessed after entering the characteristics of an enrolled participant, or serially numbered, opaque, sealed envelopes.

B = possibly adequate - for example, sealed envelopes that are not sequentially numbered or opaque.

C = inadequate - for example, open table of random numbers.

D = not described.

Blinding:

A = adequate double blinding - for example, placebo vaccine.

B = single blind - that is to say, blinded outcome assessment.

C = no blinding.

Follow up:

Average duration of follow up and number of losses to follow up.

Non-experimental studies

Quality assessment of non-randomised studies was made in relation to the presence of potential confounders, which could make interpretation of the results difficult. The quality of case control and cohort studies (prospective and retrospective) was evaluated using the appropriate Newcastle-Ottawa Scales (NOS) (*see* Appendix 2). Because of the lack of empirical evidence on the impact that the methodological quality has on the results of nonrandomised studies, this evaluation was only used at the analysis stage as a mean of interpretation of the results and a set of sensitivity analyses was performed for this scope. We classified studies as at low risk of bias (up to one inadequate item in the NOS), medium risk of bias (up to three inadequate items), high risk of bias (more than three inadequate items) and very high risk of bias (when there was no description of methods).

Arbitration procedure

In case of disagreement between two review authors VD arbitrated.

Data collection

Data extraction was performed by three review authors (TOJ, DR, and MR) using a data extraction form (*see* Appendix 3). Data were checked and entered onto customised software. Data on the following were extracted: Methodological quality of studies Study design (see Appendix 1) Description of setting Characteristics of participants Description of vaccines (content and antigenic match) Description of viral circulation degree Description of outcomes Length of the follow up Publication status Date of study

Vaccines for preventing influenza in the elderly (Review)

Location of study

Data analysis

Aggregation of data was dependent on the sensitivity and homogeneity of definitions of exposure, populations and outcomes used. Where studies were found to be homogenous, a meta-analysis of these studies was carried out within each design category.

Non-randomised and quasi-randomised evidence was analysed separately from randomised controlled trial evidence. The study results are described individually in the Results section.

We grouped reports first according to the setting of the study (community or long-term care facilities) and then by level of viral circulation and vaccine matching (when trial authors presented data according to different levels of viral circulation, only data relating to higher viral circulation were included). A period was considered "epidemic" when the weekly incidence rate exceeded the seasonal threshold. A vaccine was defined as "matching" when the vaccine strains were antigenically similar to the wild circulating strains. We further stratified by co-administration of pneumococcal polysaccharide vaccine (PPV) and by different types of influenza vaccines (live, inactivated, with adjuvant). We pooled whole, split and subunit vaccines, as in community studies this information was not reported. When a study reported data for more than one influenza season or for more than one setting, we considered these separately, creating separate data sets. We calculated the statistic I² for every pooled estimate to assess the effect on statistical heterogeneity. I² can be interpreted as the proportion of total variation among effect estimates that is due to heterogeneity rather than sampling error and it is intrinsically independent of the number of studies. When I^2 is less than 30% there is little concern about statistical heterogeneity (Higgins 2002; Higgins 2003). We used randomeffect models throughout to take account of the between-study variance in our findings (DerSimonian 1986).

When possible, we did a quantitative analysis adjusted for confounders if the cohort or case-control studies used the same methods of adjustment (logistic regression) for the same confounders. We constructed a comparison with effect sizes adjusted for the effects of possible known confounders and their standard error, which we derived from the reported confidence intervals (CIs) (Greenland 1987) and did quantitative analysis with the inverse of the variance (Deeks 2004).

Findings of one case-control study (Mullooly 1994), reporting data stratified by risk factors for influenza, were included by use of the inverse variance combining stratum-specific effect size and overall effect size.

We summarised efficacy (against influenza) and effectiveness (against influenza-like illness) estimates as relative risk (RR) using a 95% CI or odds ratio (OR) using a 95% CI). Absolute vaccine efficacy (VE) is expressed as a proportion, using the formula VE=1-RR or VE*=1-OR whenever significant. When not significant, we reported the relevant RR or OR.

To investigate the causes of heterogeneity we did a further anal-

ysis. To assess the effect of viral circulation and vaccine matching on overall heterogeneity, we calculated heterogeneity within each grouping and compared its sum with the overall heterogeneity (Greenland 1987). A sub-analysis of studies describing better defined epidemic period was performed for most significant comparisons. We then tested effect size from cohort studies done in long-term care facilities (where data are more plentiful), stratified by methodological quality of the studies.

RESULTS

Description of studies

See: Characteristics of included studies; Characteristics of excluded studies.

Efficacy and effectiveness evaluation

4400 titles of reports of potentially relevant studies were identified and screened for retrieval; 4088 reports were excluded by screening of titles and abstracts; 312 reports were retrieved for detailed assessment; 241 reports did not fulfil inclusion criteria. The most frequent reasons for exclusion were lack of presentation of original data, lack of placebo or standard care comparator and presence of antibody titres as outcomes. A complete list with reasons for exclusion is available in the tables.

Seventy-one studies were included in systematic review: 64 studies were used to assess efficacy / effectiveness and eight were included in safety assessment (one randomised controlled trial (RCT) was included in both assessments).

Sixty-four studies included in efficacy / effectiveness assessment were split into subsets by influenza season or setting or vaccine type, resulting in 96 data sets as described below:

Five RCTs resulted in five data sets (Allsup 2001; Edmondson 1971; Govaert 1994; Rudenko 2001; Stuart 1969);

Forty-nine cohort studies resulted in 79 data sets (Arden 1988; Arroyo 1984; Aymard 1979a; Aymard 1979b; Caminiti 1994; Cartter 1990a; Cartter 1990b; Cartter 1990c; Christenson 2001a; Christenson 2001b; Christenson 2004a; Christenson 2004b; Coles 1992; Comeri 1995; Consonni 2004a; Consonni 2004b; Cuneo Crovari 1980; Currier 1988; D'Alessio 1969; Davis 2001a; Davis 2001b; Deguchi 2001; Feery 1976; Fleming 1995; Fyson 1983a; Fyson 1983b; Gavira Iglesias 1987; Gené Badia 1991; Goodman 1982; Gross 1988; Hak 2002a; Hak 2002b; Horman 1986; Howarth 1987a; Howarth 1987b; Howells 1975a; Howells 1975b; Howells 1975c; Isaacs 1997; Kaway 2003; Lopez Hernandez 1994; Mangtani 2004b; Mangtani 2004c; Mangtani 2004d; Mangtani 2004e; Mangtani 2004f; Mangtani 2004g; Mangtani 2004h; Mangtani 2004i; Mangtani 2004j; Meiklejohn 1987; Monto 2001; Morens 1995; Mukerjee 1994; Murayama 1999; Nichol 1994a; Nichol 1994b; Nichol 1994c; Nichol 1998a; Nichol 1998b; Nichol 2003a; Nichol 2003b; Nicholson 1999; Nordin 2001a; Nordin

Vaccines for preventing influenza in the elderly (Review)

2001b; Patriarca 1985a; Patriarca 1985b; Pregliasco 2002; Ruben 1974; Saah 1986a; Saah 1986b; Saah 1986c; Saito 2002a; Saito 2002b; Shapiro 2003; Strassburg 1986; Taylor 1992; Voordouw 2003);

Ten case-control studies resulted in 12 data sets (Ahmed 1995; Ahmed 1997; Crocetti 2001; Fedson 1993a; Fedson 1993b; Foster 1992; Mullooly 1994; Ohmit 1999; Ohmit 1995a; Ohmit 1995b; Puig-Barberà 1997; Puig-Barberà 2004).

Half (n = 48) the data sets reported A/H3N2 virus circulating, 4% (n = 4) B viruses, 1% (n = 1) A/H1N1, 1% (n = 1) A/H2N2, and 7% (n = 7) reported A/H3N2 and A/H1N1 circulating at the same time. The remaining 37% (n = 35) of data sets did not provide sufficient information on circulating subtypes.

Twenty-three studies resulting in 38 data sets collected information about health conditions of vaccinated and unvaccinated persons and reported stratified results or adjusted rates. Subjects suffering from lung disease, heart disease, renal disease, diabetes and other endocrine disorders, immunodeficiency or immunosuppressive diseases, cancer, dementia or stroke, vasculitis and rheumatic disease were considered as belonging to risk groups.

Included studies used the recommended and licensed vaccine formulation even if some authors did not declare vaccine composition.

In RCTs, placebo was the comparison. All cohort studies compared the effects of vaccination against no vaccination.

Seven studies included in our safety assessment are described below:

Five randomised controlled trials (Govaert 1993; Keitel 1996; Margolis 1990a; Treanor 1994; Stuart 1969);

Three surveillance studies with a non-comparative design assessing rare events (GBS) (Kaplan 1982; Lasky 1998; Schonberger 1979) were commented on in the text but were not included in our meta-analysis.

See the description of the studies in the 'Characteristics of included studies' table.

Risk of bias in included studies

Quality was as follows:

Experimental

Allocation concealment: Adequate 3 Allocation concealment: Unclear 1 Allocation concealment: Inadequate 0 Allocation concealment: Not described 5

Cohort / case control

Low risk of bias 18 Medium risk of bias 29 High risk of bias 9 Very high risk of bias 3

Surveillance studies

For three surveillance studies assessing rare side effects, quality evaluation was not performed. All were population-based studies with good case findings and case-definitions.

Effects of interventions

Efficacy / effectiveness

Cohort studies in long-term care facilities

Twenty-nine cohort studies in long-term care facilities contributed data to 40 data sets (Arden 1988; Arroyo 1984; Aymard 1979a; Aymard 1979b; Cartter 1990a; Cartter 1990b; Cartter 1990c; Coles 1992; Cuneo Crovari 1980; Currier 1988; Taylor 1992; Deguchi 2001; Feery 1976; Fyson 1983a; Fyson 1983b; Goodman 1982; Gross 1988; Horman 1986; Howarth 1987a; Howarth 1987b; Howells 1975a; Howells 1975b; Howells 1975c; Isaacs 1997; Meiklejohn 1987; Monto 2001; Morens 1995; Mukerjee 1994; Murayama 1999; Patriarca 1985a; Patriarca 1985b; Ruben 1974; Saah 1986a; Saah 1986b; Saah 1986c; Saito 2002a; Saito 2002b; Strassburg 1986; Taylor 1992) and 33,985 observations. These studies were very focused and were fairly well resourced: 35 data sets reported virologic surveillance that confirmed influenza virus circulation and 22 data sets had short follow up (less than three months). They assessed the effects of vaccines in residential communities. The resident population is described in about half of the included data sets as predominantly aged older than 75 years, with multiple chronic pathologies and a high dependency level. However, breakdown of potential confounding factors (such as age, sex, smoking status and underlying chronic disease) is rarely reported by vaccine exposure, making correction of confounders impossible.

Studies recorded during outbreaks or periods of high viral circulation

Of the 40 data sets, 29 data sets (Arden 1988; Arroyo 1984; Aymard 1979a; Aymard 1979b; Cartter 1990a; Cartter 1990b; Cartter 1990c; Coles 1992; Cuneo Crovari 1980; Currier 1988; Taylor 1992; Feery 1976; Fyson 1983a; Fyson 1983b; Goodman 1982; Gross 1988; Horman 1986; Isaacs 1997; Meiklejohn 1987; Monto 2001; Morens 1995; Mukerjee 1994; Murayama 1999; Patriarca 1985a; Ruben 1974; Saah 1986a; Saah 1986b; Strassburg 1986; Taylor 1992) with a total of 6702 observations, were recorded during outbreaks or periods of high viral circulation. In 26 data sets the influenza virus subtype is positively identified (A/H3N2 in 23 data sets). The focus of 23 data sets (Arden 1988; Arroyo 1984; Cartter 1990a; Cartter 1990b; Cartter 1990c; Coles 1992; Cuneo Crovari 1980; Currier 1988; Taylor 1992; Feery 1976; Fyson

Vaccines for preventing influenza in the elderly (Review)

1983a; Fyson 1983b; Goodman 1982; Horman 1986; Isaacs 1997; Meiklejohn 1987; Morens 1995; Murayama 1999; Ruben 1974; Saah 1986a; Saah 1986b; Strassburg 1986; Taylor 1992) from 19 studies was on assessment of the effect of vaccination on single epidemic foci. Viral circulation was confirmed by isolates, increases in antibody titres, or observation of an epidemic of influenzalike illness in an institution at the same time as influenza A or B circulation in the surrounding community. A high proportion of cases classified as influenza-like illnesses were probably influenza cases. Twenty-one data sets (Arden 1988; Aymard 1979a; Cartter 1990a; Cartter 1990b; Cartter 1990c; Feery 1976; Fyson 1983a; Fyson 1983b; Goodman 1982; Gross 1988; Horman 1986; Isaacs 1997; Meiklejohn 1987; Monto 2001; Morens 1995; Mukerjee 1994; Murayama 1999; Patriarca 1985a; Saah 1986b; Strassburg 1986; Taylor 1992) from 17 studies provided information about vaccine content match with circulating influenza viruses. We thus grouped our analyses by viral circulation and vaccine match.

Twenty-one data sets assessed the effectiveness of influenza vaccines in preventing influenza-like illnesses (comparison 01.01.01 and comparison 01.01.02). In these data sets, follow up was restricted to an outbreak period (mean duration 443,116 days) and authors reported a virologic surveillance that confirmed influenza virus circulation.

The overall effectiveness of vaccines (VE) against influenza-like illnesses was 23% (6% to 36%; comparison 01.01.01) when vaccine matching was good and not significantly different from no vaccination (RR 0.77; 95% CI 0.56 to 1.06; comparison 01.01.02) when matching was poor or unknown. Heterogeneity was high, even within the same influenza season and within the same institution when data from different accommodation blocks were analysed. We noted no association (correlation coefficient 0.09) between vaccine coverage and attack rate of influenza-like illness (*see* Additional Figure 1).

Relationship between vaccination rate and attack rate

Efficacy of the vaccines against influenza was tested in only six data sets (1250 observations) (Cuneo Crovari 1980; Feery 1976; Gross 1988; Morens 1995; Ruben 1974; Taylor 1992) and was not significant both for vaccine matching (RR 1.04; 95% CI 0.43 to 2.51; comparison 01.02.01) and when matching was absent or unknown (RR 0.47; 95% CI 0.22 to 1.04; comparison 01.02.02). The effectiveness of the vaccines in preventing pneumonia was assessed in 12 data sets (comparison 01.03.01 and comparison 01.03.02; 5296 observations). All of them reported virologic surveillance and eight had follow ups shorter than three months (Arroyo 1984; Coles 1992; Currier 1988; Horman 1986; Meiklejohn 1987; Morens 1995; Patriarca 1985a; Taylor 1992). Well-matched vaccines were 46% (30% to 58%; comparison 01.03.01) effective in preventing pneumonia (Gross 1988; Horman 1986; Meiklejohn 1987; Morens 1995; Monto 2001; Patriarca 1985a; Saah 1986b; Taylor 1992). When matching was poor or unknown (Arroyo 1984; Currier 1988; Coles 1992; Saah 1986a), vaccines had no effect (RR 0.64; 95% CI 0.35 to 1.16; comparison 01.03.02). Excluding studies with the longest follow up (Gross 1988; Saah 1986a; Saah 1986b: six months) did not affect our conclusions.

Eight data sets (Arden 1988; Cartter 1990a; Cartter 1990b; Cartter 1990c; Meiklejohn 1987; Murayama 1999; Patriarca 1985a; Taylor 1992) assessed the effectiveness of well matched vaccines in preventing hospitalisation for influenza or pneumonia. All of them had a brief and well defined follow up; effectiveness was 45% (16% to 64%; comparison 01.04.01). One small study reported a non-significant effect (Coles 1992; comparison 01.04.02) when the vaccine did not match the circulating strain.

Vaccination had a significant effect on the prevention of deaths due to influenza or pneumonia, though this was in the presence of considerable heterogeneity between the 20 data sets (Arroyo 1984; Cartter 1990a; Cartter 1990b; Cartter 1990c; Coles 1992; Feery 1976; Fyson 1983a; Fyson 1983b; Goodman 1982; Horman 1986; Meiklejohn 1987; Monto 2001; Morens 1995; Murayama 1999; Patriarca 1985a; Ruben 1974; Saah 1986a; Saah 1986b; Strassburg 1986; Taylor 1992; comparison 01.05.01 and comparison 01.05.02). Eighteen studies reported virologic surveillance to confirm influenza virus circulation; of these, 16 had a follow up shorter than 3 months and two had a four month follow up (Feery 1976; Monto 2001). Two studies lacked virologic surveillance and had a six month follow up (Saah 1986a; Saah 1986b).

The vaccine was effective if it was a good match (VE 42%; 17% to 59%; comparison 01.05.01), otherwise it was not effective (RR 0.34; 95% CI 0.11 to 1.02; comparison 01.05.02).

Excluding two studies with a six month follow up and absence of viral surveillance (Saah 1986a; Saah 1986b) affects the summary estimate more than the efficacy in the "epidemic-matching" group, which drops from 42% to 39% (CI 95% 12 to 58).

The effectiveness in reducing all-cause mortality was assessed in only one small study with a six month follow up (Gross 1988) and

was significant (60%; 23% to 79%; comparison 01.06.01).

Studies carried out during low viral circulation

Eleven data sets assessing the effects of influenza vaccines in 350 institutional facilities during low viral circulation comprised of 27,283 observations (Caminiti 1994; Deguchi 2001; Howarth 1987a; Howarth 1987b; Howells 1975a; Howells 1975b; Howells 1975c; Patriarca 1985b; Saito 2002a; Saito 2002b; Saah 1986c). Apart from Patriarca 1985, in this subgroup we found studies with the longest (five to six months) and most poorly defined follow up. Two of these studies (Deguchi 2001; Saah 1986c) did not report virologic surveillance.

The vaccines were 33% effective (2% to 54%; comparison 01.01.03) in preventing influenza-like illnesses (ILI) (Caminiti 1994; Patriarca 1985b; Saito 2002a; Saito 2002b) but had no significant effects in preventing influenza (RR 0.23, 95% CI 0.05 to 1.03; comparison 01.02.03). This observations is based on two data sets from a single relatively small study (691 observations) (Howarth 1987a; Howarth 1987b). Both comparisons are from well-matched vaccines.

We identified a few data sets that assessed effectiveness of vaccines in preventing complications. Four briefly reported data sets from two studies (Howells 1975a; Howells 1975b; Howells 1975c; Saah 1986c) carried out in situations of low viral circulation and poor vaccine matching report a combined effectiveness of 65% (32% to 82%; comparison 01.03.04) in preventing pneumonia.

During periods of low viral circulation, vaccines did prevent hospital admission for pneumonia or influenza (VE 68%; 24% to 86%; comparison 01.04.03). However one of the included studies (Deguchi 2001) is at high risk of bias - meaning that this outcome may not be accurate. The study was set in 301 nursing homes, comprising 22,462 elderly participants during the nonepidemic 1998 to 1999 season in Japan. The same study has a large weight in the analysis of effectiveness against deaths by influenza and pneumonia (VE 71%; 43% to 85%; comparisons 01.05.03 and 01.05.04) (Caminiti 1994; Deguchi 2001; Howells 1975a; Howells 1975b; Howells 1975c; Patriarca 1985b; Saah 1986c).

Cohort studies in community-dwelling elderly

We included 20 studies with 39 data sets in elderly participants living in open communities (Christenson 2001a; Christenson 2001b; Christenson 2004a; Christenson 2004b; Comeri 1995; Consonni 2004a; Consonni 2004b; Davis 2001a; Davis 2001b; Davis 2001c; Fleming 1995; Gavira Iglesias 1987; Gené Badia 1991; Hak 2002a; Hak 2002b; Kaway 2003; Lopez Hernandez 1994; Mangtani 2004b; Mangtani 2004c; Mangtani 2004d; Mangtani 2004e; Mangtani 2004f; Mangtani 2004g; Mangtani 2004h; Mangtani 2004i; Mangtani 2004j; Nichol 1994a; Nichol 1994b; Nichol 1994c; Nichol 1998a; Nichol 1998b; Nichol 2003a; Nichol 2003b; Nicholson 1999; Nordin 2001a; Nordin 2001b; Pregliasco 2002; Shapiro 2003; Voordouw 2003). The studies contained over three

Vaccines for preventing influenza in the elderly (Review)

million observations mainly collected using data-linkage from insurance reimbursement, hospital or primary care data bases; 13 of them reported data stratified or adjusted by risk factors and other potential confounders. These studies had long follow ups: 12 data sets had a follow up =< 3 months, 13 data sets had a follow up ranging from four to five months, eight data sets had a follow up ranging from six to seven months; four data sets had a follow up ranging from 8 to 12 months and two data sets were without a well defined follow up. In nine data sets, follow up was defined by relying on virologic surveillance and three data sets had laboratory confirmation of cases. On the basis of this large body of evidence, we divided our analysis into six separate comparisons.

Inactivated influenza vaccines in all community dwelling elderly

Our second comparison relies on 1 million observations in 18 data sets from 15 studies (Christenson 2001a; Christenson 2004a; Comeri 1995; Davis 2001c; Fleming 1995; Gavira Iglesias 1987; Gené Badia 1991; Kaway 2003; Lopez Hernandez 1994; Mangtani 2004a; Nichol 1994a; Nichol 1994b; Nichol 1994c; Nichol 1998b; Nichol 2003a; Nichol 2003b; Nicholson 1999; Shapiro 2003; Voordouw 2003).

In elderly individuals living in the community, inactivated influenza vaccines were not effective against ILI, influenza or pneumonia. No comparison provided enough data for stratification by viral circulation and vaccine matching.

Eight data sets (779,934 observations) with medium to long follow up (135 to 365 days) addressed vaccine effectiveness against hospitalisations for influenza or pneumonia (Christenson 2001a; Christenson 2004a; Nichol 1994a; Nichol 1994b; Nichol 1994c; Nichol 1998b; Nichol 2003a; Nichol 2003b). Well-matched vaccines prevented hospital admissions for these illnesses (VE 26%; 12% to 38%; comparison 02.04.01) but not for cardiac disease (RR 0.87; 95% CI 0.67 to 1.12; comparison 02.09). Excluding the only study with a one year follow up (Christenson 2004a) effectiveness in preventing hospital admissions is increased to 29% (95% CI 14 to 42).

Death from respiratory disease was not significantly affected. Seven data sets (Fleming 1995; Gené Badia 1991; Lopez Hernandez 1994; Nichol 2003a; Nichol 2003b; Shapiro 2003; Voordouw 2003) with a follow up ranging from 75 to 210 days, assessed the effect on mortality for all causes (VE: 42%; 24% to 55%; comparison 02.08). Excluding four data sets with a follow up equal to or longer than six months (Gené Badia 1991; Lopez Hernandez 1994; Voordouw 2003) or a non-defined follow up (Shapiro 2003), the efficacy falls from 42% to 39% (95% CI 28 to 49).

Inactivated influenza vaccines in community dwelling elderly at risk of influenza complications

In the third comparison, we assessed the effectiveness of inactivated influenza vaccines in elderly individuals living in the community and at risk of complications associated with influenza. Patients with any of the following underlying conditions were considered at risk of complications: lung disease, heart disease, renal disease, diabetes and other endocrine disorders, immunodeficiency or immunosuppressive diseases, cancer, dementia or stroke, vasculitis, or rheumatic disease. Seven data sets from six studies were relevant. The only significant effect was that for deaths from all causes (VE: 61%; 3% to 84%; comparison 03.06) from 68,032 observations with high heterogeneity (I² 94.1%) (Fleming 1995; Shapiro 2003; Voordouw 2003).

Inactivated influenza vaccines in community dwelling elderly without risk of influenza complications

In this stratum, six studies with seven data sets (Fleming 1995; Hak 2002a; Hak 2002b; Mangtani 2004a; Nichol 1998a; Shapiro 2003; Voordouw 2003) contributed several hundred thousand observations. However, most outcomes were only assessed by one study. The only notable results are the vaccines' effectiveness in preventing hospital admission for influenza or pneumonia (VE: 50%; 37% to 60%; comparison 04.03) although this observation is based only on one data set Nichol 1998a with 101,619 observations, and there is a lack of effect on all-cause mortality (RR 0.65; 95% CI 0.33 to 1.29; 43,821 observations; comparison 04.06) (Fleming 1995; Shapiro 2003; Voordouw 2003).

Inactivated influenza vaccines in all community dwelling elderly (adjusted for confounders)

This is another data set with 7 studies contributing 19 data sets (Davis 2001a; Davis 2001b; Davis 2001c; Fleming 1995; Mangtani 2004b; Mangtani 2004c; Mangtani 2004d; Mangtani 2004e; Mangtani 2004f; Mangtani 2004f; Mangtani 2004j; Nichol 1998a; Nichol 2003a; Nichol 2003b; Nordin 2001a; Nordin 2001b; Voordouw 2003) with over a million observations from several consecutive influenza seasons. Most of the studies included in this analysis used data linkage and adjusted their OR calculations to allow for the effect of confounding of several variables (sex, age, smoking, co-morbidities). The effects of the vaccines are all significant.

Hospitalisations for influenza or pneumonia: 8 data sets, all but one with a follow up lasting 135 days (Davis 2001a; Davis 2001b; Davis 2001c; Nichol 1998a; Nichol 2003a; Nichol 2003b; Nordin 2001b). OR 0.73; 95% CI 0.67 to 0.79, based on 949,215 observations (comparison 07.01). Excluding the only data set (Nordin 2001a) with the longest follow up (eight months) does not change the result.

Hospitalisations for respiratory diseases OR 0.78; 95% CI 0.72 to 0.85 (comparison 07.02). Data sets have a follow up of 135 days or less, so a sensitivity analysis appears to be superfluous.

Hospitalisation for cardiac disease OR 0.76; 95% CI 0.70 to 0.82 (comparison 07.03). Data sets have a follow up of 135 days or less, so a sensitivity analysis appears to be superfluous.

Mortality for all causes: seven data sets (Fleming 1995; Nichol 1998a; Nichol 2003a; Nichol 2003b; Nordin 2001a; Nordin 2001b; Voordouw 2003) with follow up ranging from 75 to 240 days. OR 0.53; 95% CI 0.46 to 0.61(comparison 07.04). Excluding data sets with a follow up period equal to or longer than 6 months (Nordin 2001a; Voordouw 2003) does not change the final result.

Inactivated influenza and **PPV** on community dwelling elderly

Three studies assessed the impact of inactivated influenza and concomitant PPV (Christenson 2001b; Christenson 2004b; Consonni 2004b) on hospitalisations for influenza or pneumonia or respiratory diseases (VE = 33%; 30 to 36 %, based on 518,748 observations; comparison 05.02) and two data sets (Christenson 2001b; Consonni 2004b) assessed the effect on all causes mortality (VE = 56%; 54% to 59%; comparison 05.04).

The addition of PPV did not appear to significantly improve the performance of influenza vaccines.

Adjuvant influenza vaccines in all community dwelling elderly

Two small studies with a combined denominator of 498 assessed the impact of vaccines containing a virosomal adjuvant in preventing ILI (VE 70%, 44% to 84%; comparison 06.01) and hospitalisations (RR 0.17; 95% CI 0.02 to 1.28; comparison 06.02.03) during a year of low viral circulation but with a vaccine with a good match (Consonni 2004a; Pregliasco 2002). The study by Consonni 2004a also assessed the impact on mortality for all causes and found no effect (RR 2.10; 95% CI 0.10 to 43.10; comparison 06.03.03). This is not surprising given its population size of 129 patients (too small for any significant effect to be evident).

Case-control studies

We included 10 studies contributing 12 data sets (Ahmed 1995; Ahmed 1997; Crocetti 2001; Fedson 1993a; Fedson 1993b; Foster 1992; Mullooly 1994; Ohmit 1995a; Ohmit 1995b; Ohmit 1999; Puig-Barberà 1997; Puig-Barberà 2004). Six data sets from five studies assessed the effects of inactivated influenza vaccines on community dwelling elderly (Ahmed 1995; Ahmed 1997; Crocetti 2001; Fedson 1993a; Fedson 1993b; Puig-Barberà 1997), five looked at the co-administration of inactivated influenza with PPV on institutionalised elderly (Foster 1992; Mullooly 1994; Ohmit 1995a; Ohmit 1995b; Ohmit 1999) and one of adjuvant influenza with PPV on community-dwelling elderly (Puig-Barberà 2004). Only three of these studies, all assessing influenza and pneumococcal vaccines, had a long follow up (six months). Since all data sets adjusted their ORs for likely confounding factors, we structured our analysis on five strata, further subdividing each analysis by viral circulation and vaccine matching whenever possible.

Inactivated influenza vaccines on community dwelling elderly

Before adjustment, inactivated influenza vaccines were associated with an increased risk of admission for any respiratory disease (OR 1.08; 95% CI 0.92 to 1.26; 20,582 observations; comparison 08.02.01) (Ahmed 1997; Fedson 1993a; Fedson 1993b) and did not prevent hospital admission for influenza and pneumonia in elderly individuals living in the community (OR 0.89; 95% CI 0.69 to 1.15; 1074 observations; comparison 08.01) (Crocetti 2001; Puig-Barberà 1997) or affect mortality from influenza and pneumonia, though this conclusion is based on a relatively small data set of 1092 observations (Ahmed 1995; comparison 08.03.01).

Inactivated influenza vaccines on community dwelling elderly - adjusted analysis

After adjustment, however, the vaccines did reduce the risk of death from influenza and pneumonia (OR 0.74; 95% CI 0.60 to 0.92; comparison 11.03) (Ahmed 1995; Mullooly 1994) and prevent admission for influenza and pneumonia (OR 0.59; 95% CI 0.47 to 0.74; comparison 11.01) (Crocetti 2001; Foster 1992; Mullooly 1994; Puig-Barberà 1997; Puig-Barberà 2004) and for all respiratory diseases (OR 0.71; 95% CI 0.56 to 0.90; comparison 11.02) (Ahmed 1997; Fedson 1993a; Fedson 1993b).

Inactivated influenza and PPV vaccines

Similarly, before adjustment inactivated influenza and concomitant PPV in individuals living in the community did not prevent hospital admission for influenza and pneumonia (OR 0.97; 95% CI 0.85 to 1.09; comparison 09.01) (Foster 1992; Ohmit 1995a; Ohmit 1995b; Puig-Barberà 2004), whereas after adjustment they did (OR 0.68; 95% CI 0.54 to 0.86; comparison 12.01) (Ohmit 1995a; Ohmit 1995b). One study assessed effect of influenza and PPV vaccines on ILI: VE 48%; 32% to 60%; 1198 observations; comparison 10.01(Ohmit 1999).

RCTs

We identified five randomised controlled trials published over four decades and including just over 5000 observations (Allsup 2004; Edmondson 1971; Govaert 1994; Rudenko 2001; Stuart 1969). Given the heterogeneous nature of the vaccines tested (monvalent, trivalent, live, or inactivated aerosol vaccines), setting, follow up and outcome definition, no firm conclusions can be drawn from this body of evidence. Follow up is only specified in three trials (Govaert 1994; Rudenko 2001; Stuart 1969) and ranges from 42 to 180 days. Two trials had adequate randomisation and allocation concealment, and one trial had adequate measures to prevent attrition bias. The results of the most recent trial (Allsup 2004) are difficult to interpret because of the presence of selection bias. Based on the results of a meta-analysis of two trials (Allsup 2004; Govaert 1994), inactivated vaccines were more effective than placebo against ILI in conditions of high viral circulation

Vaccines for preventing influenza in the elderly (Review) Copyright © 2008 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

among elderly individuals living in the community (VE 43%; 21% to 58%; comparison 13.01.01). The vaccines were also effective against influenza (VE 58%; 34% to 73%; comparison 13.02) (Edmondson 1971; Govaert 1994; Rudenko 2001).

Possible causes of observed heterogeneity - post hoc analysis

Of the 15 main comparisons with 61 outcome combinations, we noted in a subsequent analysis that seven comparisons with 20 outcome combinations had an I² of greater than 30% and that the heterogeneity of these studies could be explained by grouping by viral circulation and vaccine matching. In additional tables we reported comparisons in which statistical heterogeneity could be explained by differences in viral circulation and degree of vaccine matching or study quality. We used the following keys: statistical heterogeneity could be explained by: (*) differences in viral circulation and degree of vaccine matching; (°) differences in study quality; (+) insufficient data, () not statistically significant (that is, heterogeneity in outcomes not explained by either viral circulation, vaccine matching or study quality groupings). All tests performed were performed at the 10% level of significance

Safety

We included data on local and systemic side effects. For local side effects we included tenderness, sore arm, swelling, erythema and induration. Similar local symptoms were pooled in the analysis due to small data sets. Systemic symptoms were general malaise, fever, headache, nausea and respiratory tract symptoms.

Four RCTs (Govaert 1993; Keitel 1996; Margolis 1990a; Treanor 1994; comparison 17) reported data about local and systemic adverse events observed within a week from administration of parenteral inactivated vaccine (2606 observations). Treanor 1994 also reported data about live aerosol vaccine (comparison 18). All side effects reported in trials were included in the analysis, even if they were not significant. Vaccines usually induced systemic side effects (general malaise, fever, nausea, headache) more frequently than placebo, but no outcome showed statistically significant results. Local adverse events as tenderness and sore arm were significantly more frequent in the treatment arm than in the placebo arm. The only studies assessing rare adverse events were three surveillance studies assessing GBS with neither cohort nor case control design (Kaplan 1982; Lasky 1998; Schonberger 1979; Table 1). Case finding was carried on by interviewing neurologists or by searching discharge diagnoses databases. Vaccination rates in the relevant populations were estimated from specific survey or from national immunisation survey. All studies were conducted in the USA and assessed the entire population irrespective of age. Lasky 1998 and Schonberger 1979 reported outcome stratified by age, allowing data extraction for elderly people. We reported results of these studies in 'Guillain Barré Syndrome' table. The strong and significant association between A/New Jersey/76 swine vaccine and GBS, during the 1976 to 1977 influenza season was not confirmed in subsequent seasons when other vaccines not containing A/New Jersey/76 were used.

Study	Influenza season	Vaccine	Population	Age	RR (95% CI)
Schonberger 1979	1976 to 1977	A/New Jersey/76 or A/New Jersey/76 and A/Victoria/75 swine vaccine	All the USA pop.	> 64 years	5.2 (3.9 to 7.0)
Kaplan 1982	1979 to 1980	Inactivated trivalent	All the USA pop.	> 18 years	0.6 (0.45 to 1.32)
Kaplan 1982	1980 to 1981	Inactivated trivalent	All the USA pop.	> 18 years	1.4 (0.80 to 1.76)
Lasky 1998	1992 to 1994	Inactivated trivalent	21 million	> 64 years	1.5 (0.7 to 3.3)

Vaccines for preventing influenza in the elderly (Review)

DISCUSSION

Our findings show that according to reliable evidence, the effectiveness of trivalent inactivated influenza vaccines in elderly individuals is modest, irrespective of setting, outcome, population and study design. Our estimates are consistently below those usually quoted for decision or economic model making. In view of the known variability of incidence and effect of influenza, we constructed a large number of comparisons and strata to reduce possible heterogeneity between studies to a minimum and aid comparability. We also performed sub-analysis of studies describing better defined epidemic periods. Despite our attempts, we noted significant residual heterogeneity between studies that could be explained only in part by different study designs, methodological quality, settings, viral circulation, vaccine types and matching, age, population types and risk factors. We think the residual heterogeneity could be the result of the unpredictable nature of the spread of influenza and ILI and the bias caused by the non-randomised nature of our evidence base. Our sensitivity analysis did not affect the final result.

Our main concern was the quality of included studies which probably affected the estimates of effect reported in our review. The findings of the cohort studies that we included are likely to have been affected to a varying degree by selection bias. Differential uptake of influenza vaccines is linked to several factors (anxiety over unwanted effects, disease threat perception, societal and economic conditions, education, health status) and hence to outcome. Confounding by indication (people with chronic illness or people who are perceived to be frailer than others are more likely to be vaccinated) might reduce the estimated vaccine efficacy. People with terminal illness or with socio-economic disadvantages are less likely to be vaccinated and this fact might enhance vaccine efficacy. For example, one cohort study (Gené Badia 1991) had difficulties achieving high coverage in those most at need. Differential vaccine uptake and the resulting selection bias is the most likely explanation for the high effectiveness of influenza vaccines in preventing deaths from all causes. A further example of the potential effect of such bias is the apparently counter-intuitive effectiveness of the vaccines in elderly individuals living in the community. In this population, the vaccines are apparently ineffective in the prevention of influenza, ILI, pneumonia, hospital admissions or deaths from any respiratory disease but are effective in the prevention of hospital admission for influenza and pneumonia and in the prevention of deaths from all causes.

It cannot be discounted that such differences are the result of a baseline imbalance in health status and other systematic differences in the two groups of participants. Recently, empirical confirmation of the presence of selection bias in cohort studies assessing the effectiveness of influenza vaccines has been presented. The rationale of the work starts from the observation that the 47% reduction in

risk of all-cause mortality in elderly community dwellers observed in our review exceeds by far the estimated possible impact of influenza on winter-seasonal mortality of 5% in an average season (Glezen 2006; Simonsen 2005). Proof of bias was provided by a study evaluating the risk of hospitalisation and death in vaccinated compared with unvaccinated seniors in both influenza and noninfluenza periods (Jackson 2006a). Consistent with other published studies, during influenza season, vaccination was associated with a 44% reduction in risk of all-cause mortality. However, in the period before influenza the season, vaccination was associated with a 61% reduction in risk of this outcome. The reduction in risk before influenza season indicates the presence of bias due to preferential selection of vaccination by relatively healthy seniors, and the strength of that bias is sufficient to account entirely for the association found during influenza season. In a second, nested case-control, seniors with functional markers of frailty (such as dependence on washing) were found to be at greatly increased risk of death and were less likely to have received influenza vaccine, indicating that these factors are important sources of bias in assessment of influenza vaccine effectiveness (Jackson 2006b). Until improvement of cohort study design is available, the use in nonrandomised studies of highly non specific outcome indicators such as all-cause mortality - are likely to lead to unrealistic estimates of the effects of the vaccines.

Evidence from RCTs, in which bias is reduced to a minimum, is scant and badly reported. Unfortunately, because of the global recommendations on influenza vaccination, placebo-controlled trials, which could clarify the effects of influenza vaccines in individuals, are no longer possible on ethical grounds.

Whatever the causes of observed variability, we believe that the decision to vaccinate against influenza cannot be made on the basis of the results from single studies, reporting observations from a few seasons, but that it should be taken on the basis of all available evidence. The conclusions drawn from studies done in individuals who live in long-term care facilities are different to those drawn from studies in individuals who live in the community. Whereas studies done in residents of care homes often indicate the inevitably improvised nature of efforts to study the effect of vaccines during an epidemic. Often concurrently in several locations, the resident population is usually more homogeneous than that in the community: older, with similar viral exposure and risk levels. Despite a remaining heterogeneity and an overestimation of the effects as a result of study design, it is possible to detect a gradient of effectiveness, in which vaccines have little effect on cases of ILI, but have greater effect on its complications. This finding suggests that control through vaccination is a possibility. However, the effectiveness of vaccines in the community is modest, irrespective of adjustment for systematic differences between vaccine recipients and non-recipients. The difficulties of achieving good coverage in those who most need it or the diluting effect on vaccines for influenza of other agents circulating in the community (causing ILI,

clinically indistinguishable from influenza), might be to blame. We noted empirical proof of both these possibilities, with differential vaccine uptake among the same population (linked to age, sex, and health status) and a low effect on ILI throughout our data sets even in periods of supposedly high influenza viral circulation, when the proportion of cases of ILI caused by influenza and the possible benefits of vaccination are highest.

Safety does not appear to be a particular problem: the public health safety profile of the vaccines is acceptable.

AUTHORS' CONCLUSIONS

Implications for practice

Efforts should be concentrated on achieving high vaccination coverage in long-term care facilities coupled with a systematic assessment of the effect of such a policy. One possible way to improve this strategy may be to also vaccinate carers in an effort to reduce transmission. More comprehensive and effective strategies for the control of acute respiratory infections should be implemented, which may rely on several preventive interventions that take into account the multi-agent nature of ILI and its context (such as personal hygiene, provision of electricity and adequate food, water and sanitation). The effect of vaccination of high risk groups should also be further assessed.

Implications for research

Investment in the development of better vaccines than are presently available should be linked to better knowledge of the causes and patterns of ILI in different communities. The additional effects of vaccinating carers in reducing transmission in nursing homes should be assessed. The effect of vaccination of high risk groups should also be further assessed.

Investment in the development of better vaccines than available at present should be linked to better knowledge of the causes and patterns of ILI in different communities. The additional effects of vaccinating carers in reducing transmission in nursing homes should be assessed. The effect of vaccination of high risk groups should also be further assessed.

ACKNOWLEDGEMENTS

We are very grateful to Dr Simonsen for her useful and shrewd remarks which we have included in our conclusions. The authors also wish to thank the following people for commenting on the draft review: Amy Zelmer, Laila Tata, Wendy Keitel, Sree Nair and Geoff Spurling.

CHARACTERISTICS OF STUDIES

Characteristics of included studies [ordered by study ID]

Item	Authors' judgement Unclear	Description B - Unclear	
Risk of bias			
Notes	Two exposure definitions were used: current vaccinees and previous vaccinees (vaccinated between 1985 and 1989) the first was used; pneumococcal vaccination was very unlikely; circulating strain was A/England/308/89. The season was an epidemic one. The study controls for confounders in analysis: health status, previous vaccination. Quantitative analysis was also performed		
Outcomes	Certified influenza death		
Interventions	Parenteral influenza vaccine. Vaccine strains matched the circulating strain		
Participants	1092 people 16 years or older; 412 cases and 1256 controls were identified; 315 and 7 the analysis respectively	'77 were included in	
Methods Case control study conducted in England, during the 1989 to 1990 influenza season, Data sources were: death certificates, general practitioner records. Follow up period v 23/2/90. Cases died from influenza during the 1989 epidemic; controls died in the sar and were matched for age, sex and residence			

Ahmed 1995

Vaccines for preventing influenza in the elderly (Review)

Methods	Case control study conducted in England, during the 1989 to 1990 influenza season, in	the community	
Weillous	Data sources were: hospital and general practitioner records. Follow up period was 1/12/ Cases were hospitalised and their discharge diagnosis or cause of death was pneumonia, emphysema or bronchitis; community controls were matched for age and sex. Specific c matched for cases who died: controls died 6 to 12 months later	89 to 31/1/90. influenza,	
Participants	445 patients admitted to hospital (303 cases were identified; 156 cases and 289 controls the analysis respectively), 16 years or older	were included in	
Interventions	arenteral influenza vaccine. Vaccine strains matched the circulating strain		
Outcomes	Hospitalisation from pneumonia, influenza, emphysema or bronchitis (ICD 466, 480.9 to 482.9, 485 to 492.8)		
Notes	Two exposure definitions were used: current vaccinees and previous vaccinees (vaccinated between 1985 and 1989): the first was used; pneumococcal vaccination was very unlikely; circulating strain was A/England/308/89. The season was an epidemic one. The study controls for confounders in analysis: health status, previous vaccination. Quantitative analysis was also performed		
Risk of bias

Allsup 2004

Methods	Experimental study conducted in Liverpool, UK during the 1999 to 2000 influenza seas	on, randomised,		
	single blind, placebo controlled. Computer random number generation. Opaque envelopes were serially numbered to assign participants to intervention. Data sources were self administered qu and medical records. Follow up period was the entire winter season			
Participants	729 community dwelling elderly without risk factors (552 treated and 177 controls, all i analysis), 65 to 74 years old) community dwelling elderly without risk factors (552 treated and 177 controls, all included in the lysis), 65 to 74 years old		
Interventions	Parenteral influenza vaccine: A/Beijing/262/95; A/Sidney/5/97: B/Beijing/184/93. All patients received oneumococcal vaccine, too. Vaccine strains matched the circulating strains			
Outcomes	Clinically defined ILI (all of the following symptoms: sudden onset, fever, cough, prostra myalgia, widespread aches), pneumonia, hospitalisation for any respiratory illness, death			
Notes	The study year was an epidemic one; the vaccine was the recommended one			
Risk of bias				
Item	Authors' judgement	Description

Vaccines for preventing influenza in the elderly (Review) Copyright © 2008 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
Arden 1988

Methods Authors investigated an outbreak in a nursing home, in Atlanta, USA, during the 1984 to 19 season; active surveillance; medical records were reviewed. Follow up period was 26/1/85 to Pharyngeal swab and paired sera were collected to confirm diagnosis		
	That yngear swab and parter sera were concered to commin diagnosis	
Participants	55 nursing home residents (31 treated and 24 controls, all included in the analysis) mean age 85 years	
Interventions	Parenteral influenza vaccine: A/Philippines/2/82; A/Chile/83; B/URSS/84. Vaccine strains probably matched circulating strains	
Outcomes	clinically defined ILI (fever 38,7°C or greater, cough, coryza, sore throat); hospitalisation from ILI; ILI severity (not extracted)	
Notes	7 day after the outbreak started all residents were given amantadine. Successive outcome were not accounted for. The circulating strain was related to A/Philippines/2/82

Arroyo 1984

Methods	Authors investigated an outbreak in a nursing home, in Columbia, UK, during the 1982 to 1	983 influenza
season; active surveillance by home staff. Follow up period was 31/1/83 to 25/2/83. Pha paired sera were collected to confirm diagnosis from 13 and 32 patients respectively		
Participants	116 nursing home residents (26 treated and 90 controls, all included in the analysis) with underlying illnesses 30 to 108 years old (mean age 71 years)	
Interventions	Parenteral influenza vaccine: A/Brazil/11/78; A/Bangkok/1/79; B/Singapore/79. Vaccine strains did not match circulating strains	
Outcomes	ILI (any acute respiratory tract infection occurring during outbreak, with or without fever), pneumonia, death from respiratory disease	
Notes	10 patients were given amantadine: not indicated if vaccinees or unvaccinated. The circulating strain was related to A/Philippines/2/82	
Risk of bias

Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Fedson 1993b

Methods	Case control study conducted in Manitoba, Canada during the 1985 to 1986 influenza season, in the community. Data sources were: insurance claim records. Follow up period was 1/12/85 to 15/2/86. Cases were admitted to the hospital with a lower respiratory tract condition as first diagnosis; community controls were matched for age, sex and residence	
Participants	9666 non-institutionalised persons, 70% were older than 65 years (2417 cases and 7249 controls, all included in analysis)	
Interventions	Parenteral influenza vaccine . Vaccine strains matched the circulating strain	
Outcomes	Hospitalisation from a lower respiratory tract condition (ICD 466, 480-487, 490-496, 500-519), deaths from any respiratory condition, deaths from all causes. Data about deaths were not reported	
Notes	Circulating strain: A/Philippines/2/82-like. The season was an epidemic one. The study controls for confounders in analysis: health status. Quantitative analysis was also performed	
Risk of bias		
Item	Authors' judgement Description	
Allocation concealment?	Yes A - Adequate	

Feery 1976

Methods	Prospective cohort study conducted in Melbourne, Australia during the 1976 influenza season. Authors investigated an outbreak in a nursing home; Follow up period was from mid-April to mid-August. Three swab and paired sera specimens were obtained from residents	
Participants	222 nursing home residents (154 treated and 68 controls, all included in the analysis); eld	lerly
Interventions	Parenteral influenza vaccine: A/Victoria/3/75; A/Scotland/840/74; B/Hong Kong/8/73 . matched circulating strains	Vaccine strains
Outcomes	Laboratory confirmed influenza, deaths from influenza	
Notes	Poor reporting; no confounder's control. The circulating strain was A/Victoria/3/75	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	No	C - Inadequate

Fleming 1995

Methods	Retrospective cohort study conducted in UK, during the 1989 to 1990 influenza season, in the commu	nity
Wethous	Data source was the general practitioner database. Follow up period was 1/11/89 to 15/1/90. As vacci used in 1988 and 1989 were antigenically closely related, two exposure definitions were used: recently vaccinated and previously vaccinated	ine
Participants	9391 residents who had at least a general practitioner's consultation in previous months (599 treated a 8792 controls, all included in the analysis), 55 years or older	and
Interventions	Parenteral influenza vaccine: A/Shanghai/1197-like. Vaccine strains matched the circulating strain	
Outcomes	Death, death or severe respiratory illness, death or any respiratory illness without further specification	
Notes	Important epidemic year. The study controls for confounders in analysis: age, gender, health status. Da were stratified by health status: people with minor underlying conditions are considered as healthy. Subje vaccinated during the previous year are considered as "non vaccinated". Quantitative analysis was also performed	
Risk of bias		
Item	Authors' judgement Descrip	tion
Allocation concealment?	Unclear B - Uncl	lear

Foster 1992

Methods	Case controlled study conducted in Michigan, USA during the 1989 to 1990 influenza sease community. Data sources were: discharge diagnoses, mailed questionnaire. Follow up period to 30/4/90. Cases were admitted to the hospital with pneumonia or influenza; community corrandomly selected	was 1/11/89
Participants	1907 non institutionalised persons (1354 cases and 2389 controls, were identified; 721 and included in analysis respectively), 65 years or older	1786 were
Interventions	Parenteral influenza vaccine; 35% of cases and 28% of controls received pneumococcal vacc Vaccine strains matched the circulating strain	ination.
Outcomes	Hospitalisation from pneumonia and influenza (ICD 480.8-483, 484.7-487.1)	
Notes	Circulating strain: A/Shanghai/11/87. The season was an epidemic one. The study controls for in analysis: health status, flu activity, pneumococcal vaccination, smoke. Peak data were used. analysis was also performed	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Fyson 1983a

Methods	Authors investigated an outbreak in a nursing home, in Canada, during the 1982 to 1983 influenza a active surveillance. Follow up period was 3/11/82-17/1/83. Throat swab and paired sera specimens	
Participants	obtained from some residents 545 chronically ill nursing home residents (321 treated and 224 controls, all included in the analyst to 103 years old, mean age 80 years	is); 18
Interventions	Parenteral influenza vaccine, whole and subvirion: A/Brazil/11/78; A/Bangkok/1/79; B/Singapore/222/79. Vaccine strains probably matched circulating strains	
Outcomes	Acute respiratory symptoms: fever, congestion, cough, sore throat, general malaise) without a clear definition; death from pneumonia	
Notes	Poor reporting; no confounder's control. Circulating strain: A/Bangkok/1/79-like; no other viruses identified	were
Risk of bias		
Item	Authors' judgement Descr	ription
Allocation concealment?	Unclear B - U	nclear

Fyson 1983b

Methods	Authors investigated an outbreak in a nursing home in Canada during the 1982 to 1983 influenza seaso partial surveillance for delayed notification of outbreak. Follow up period was 30/11/82 to 9/1/83. Three swab and paired sera specimens were obtained from some residents	
Participants	171 female, chronically ill nursing home residents (53 treated and 118 controls, all included in the analysis); 19 to 105 years old	
Interventions	Parenteral whole influenza vaccine: A/Brazil/11/78; A/Bangkok/1/79; B/Singapore/222/80. Vaccine strains probably matched circulating strains	
Outcomes	Clinically defined ILI without further specification; death from pneumonia	
Notes	Poor reporting; no confounder's control. Circulating strain: A/Bangkok/1/79-like	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Gavira Iglesias 1987

Methods	Prospective cohort study conducted in Spain, during the 1984 to 1985 influenza season, in the communi Data source was a questionnaire retrospectively applied by investigators in June to July 1985 (door-to-do survey). The whole population of a rural village was investigated	
Participants	268 community dwelling (188 treated and 80 controls, all included in the analysis) , 65 years or older	
Interventions	Parenteral influenza vaccine: A/Philippines/2/82; A/Chile/1/83; B/USSR/100/83. Matching unknown	
Outcomes	Clinically defined ILI (fever 39°C or more, chills, general malaise, myalgia, headache, arthralgia, conjunctivitis, lasting 3 days or more)	
Notes	None of the observed deaths was due to flu-related illness. The season had low epidemic levels. Subgroup analysis was performed but only for the whole population	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	No	C - Inadequate

Gené Badia 1991

Methods	Prospective cohort study conducted in Spain, during the 1988 to 1989 influenza season, in	the community.
	Data sources were: the health centre register, death certificate archives, hospital records. Follow up period was 1/11/88 to 30/5/89. In the first of the 4 health centres all elderly residents were enrolled; in the others only patients approaching the center for health reasons were enrolled	
Participants	4558 people enrolled at 4 health centres (1998 treated and 2560 controls, all included in the analysis), 65 years or older, mean age 74 years	
Interventions	Parenteral influenza vaccine. Vaccine strains matched the circulating strain	
Outcomes	All hospitalisations and hospitalisation from cardio respiratory causes (ICD 401-414 and 460-519); death from all causes. Only deaths for all causes are included in analysis	
Notes	The season was an epidemic one	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Goodman 1982

M	eth	ods	5

Authors investigated an outbreak in a nursing home, in Atlanta, USA during the 1980 to 1981 influenza

Vaccines for preventing influenza in the elderly (Review)

Goodman 1982		
(Continued)	season; medical charts and hospital charts were reviewed. Follow up period was 12/12/80 to 21/1/81. Throat swab and paired sera specimens were obtained from some residents	
Participants	120 nursing home residents (36 treated and 84 controls, all included in the analysis); 47 to 95 years old (median age 80 years). Patients required intermediate and skilled nursing care	
Interventions	Parenteral influenza vaccine: A/Bangkok/1/79; A/Brazil/11/78; B/Singapore/222/78. Vaccine strains probably matched circulating strains	
Outcomes	Clinically defined ILI (fever 37.7°C or greater or cough in the outbreak period (12/12/80 to 21/1/81), death from ILI. Hospitalisation and pneumonia were also accounted for but results were not presented by immunisation status	
Notes	No confounders' control. The circulating strain was A/Bangkok/1/79-like. Serological teste were negative for other pathogens	
Risk of bias		
Item	Authors' judgement Descriptio	
Allocation concealment?	Unclear B - Unclea	

Govaert 1993

Methods	Experimental study conducted in Netherlands, during the 1991 to 1992 influenza seasor	randomized
Trictificas	double blind, placebo controlled; randomisation scheme was stratified according to health status. Follow up period was 48 hours after vaccination. Adverse reaction were self reported on postal questionnaire	
	completed 4 weeks after vaccination	lucstionnanc
Participants	1838 not known as belonging to high risk group (927 treated and 911 controls; 23 and 9 dropped out respectively), 60 years or older	
Interventions	Parenteral influenza recommended vaccine: A/Singapore/6/86; A/Beijing/357/89; B/Beijing/1/97; B/Panama/45/90	
Outcomes	Local: swelling, itching, warm feeling, pain when touched, constant pain, discomfort. Systemic: fever, headache, malaise, other complaints	
Notes	Side effects were reported for all subjects and by risk condition. Data regarding all population were included	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Govaert 1994

Methods	Experimental study conducted in Netherlands, during the 1991 to 1992 period, in the community. Fo up period was 1/11/91 to 30/4/92. Randomised, double blind, placebo controlled; randomisation sch was stratified according to health status	
Participants	1838 persons not known as belonging to high risk group (927 treated and 911 controls; 25 and 22 dro out respectively), 60 years or older	
Interventions	Parenteral influenza recommended vaccine: A/Singapore/6/86; A/Beijing/357/89; B/Beijing/1/97; B/Panama/45/90. Vaccine strains matched the circulating strains	
Outcomes	Clinically defined ILI; laboratory confirmed ILI; several definition for clinical and laboratory ILI were tested: the Dutch Sentinel Stations definition is used (fever 37.8°C or greater + cough or coryza or sore throat or headache or myalgia)	
Notes	The study year was an epidemic one; data were stratified by health status. Intention to treat analysis was performed	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Gross 1988

Methods	Prospective cohort study conducted in New York, USA during the 1982 to 1983 influenza season. Authors investigated an outbreak in a nursing home; independent blind assessment was conducted. Follow up	
	period was 1/11/82 to 30/4/83. 305 of the 525 residents volunteered to participate to stu made without knowledge of vaccination status	idy; diagnosis was
Participants	305 nursing home residents, mostly ambulatory (181 treated and 124 controls, 138 and 94 had serologic surveillance respectively); groups were comparable for health status and drug use ; mean age 85 years	
Interventions	Parenteral influenza vaccine: A/Bangkok/1/79; A/Brazil/11/78; B/Singapore/222/79. Vaccine strains matched circulating strains (slight drift)	
Outcomes	Laboratory confirmed influenza (4-fold increase in antibody titre), Rx confirmed pneumonia, deaths from all causes	
Notes	Pneumococcal vaccine was rarely used. Amantadine was not used. The circulating strain was A/Arizona/80 closely related to A/Bangkok/1/79. Laboratory confirmed cases were analysed by intention to treat	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Hak 2002a

Methods	Prospective cohort study conducted in USA , during the 1996 to 1997 influenza season, in the commun Data source was a 3 managed care organisation database. Follow up period was 5/10/96 to 3/5/97	
Participants	122,974 members of a medical care program continuously enrolled for the 1 year period (71,005 treat and 51,969 controls, all included in the analysis), 65 years or older	
Interventions	Parenteral influenza vaccine . Vaccine matched the circulating strain	
Outcomes	Combined outcome: hospitalisation from influenza and pneumonia (ICD 480-487) or death from all causes	
Notes	"The study controls for confounders in analysis: age, gender, health status. Data were presented by hea status. None information about pneumococcal vaccination. The season was an epidemic one"	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Hak 2002b

Methods Prospective cohort study conducted in USA, during the 1997 to 1998 influenza seaso		
	Data source was the 3 managed care organisation database. Follow up period was 23/1	
Participants	158,454 members of a medical care program continuously enrolled for the 1 year period (92,001 trea and 66,453 controls, all included in the analysis), 65 years or older	
Interventions	Parenteral influenza vaccine . Vaccine did not match the circulating strain	
Outcomes	Combined outcome: hospitalisation from influenza and pneumonia (ICD 480-487) or death from all causes	
Notes	The study controls for confounders in analysis: age, gender, health status. Data were presented by status. None information about pneumococcal vaccination. The season was an epidemic one; circu strain: A/Sydney like	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Horman 1986

Methods	Authors investigated an outbreak in a nursing home, in Maryland, USA during the 1980 to 1981 influenza
	season; resident's medical records were reviewed. Follow up period was 8/12/80 to 13/1/81. Throat swab

Horman 1986		
(Continued)		
	and paired sera specimens were obtained from some residents	
Participants	159 nursing home residents 62 to 100 years old (100 treated and 59 controls, all included in the analysi most of the resident were chronically ill; risk status did not vary between vaccinees and unvaccinated	
Interventions	Parenteral influenza vaccine: A/Brazil; A/Bangkok; B/Singapore. Vaccine strains matched circulating strains	
Outcomes	Clinically defined ILI (two case definitions; more specific definition was used: fever + cough or chest congestion), pneumonia without further specification and case fatality rate	
Notes	Vaccination was not offered to staff. 36% of the observed deaths during the epidemic period occurred from causes other than flu. Circulating strains: A/Taiwan/1/79-like, very similar to the vaccine strain A/Bangkok. Isolation attempt for other pathogens were unsuccessful	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Howarth 1987a

Methods	Prospective cohort study conducted in Australia in 17 nursing homes, during the 1983 influenza season. Follow up period was autumn to spring; blinded assessment of illness was performed	
Participants	residents in 17 nursing homes (229 treated and 97 controls, all included in the analysis), 44 to 99 s old	
Interventions	Parenteral influenza vaccine: A/Victoria/186/82; A/Philippines/2/82; B/Singapore/222/79. Vaccine strain matched circulating strains	
Outcomes	Laboratory confirmed influenza (4-fold increase in antibody titre)	
Notes	Poor description of methods; part of another study. The circulating strain was A/Philippines/2/82. None information about flu activity	
Risk of bias		
Item	Authors' judgement Descrip	otion
Allocation concealment?	Unclear B - Unc	lear

Howarth 1987b

Methods	Prospective cohort study conducted in Australia in 17 nursing homes, during the 1984 influenza season.
	Follow up period was autumn to spring; blinded assessment of illness was performed

Howarth 1987b		
(Continued) Participants Interventions	365 residents in 17 nursing homes (184 treated and 181 controls, all included in the analysis), 44 to 99 Parenteral influenza vaccine: A/Dunedin/27/83; A/Philippines/2/82; B/Singapore/222/80. Vaccine strains matched circulating strains	
Outcomes	Laboratory confirmed influenza (4-fold increase in antibody titre)	
Notes	Poor description of methods; part of another study. The circulating strain was A/Philippin information about flu activity	nes/2/82. None
Risk of bias		
Item	Authors' judgement	Description

Howells 1975a

Methods	Prospective cohort study conducted in UK in several nursing homes, during the 1971 to 1972 influenz season; all residents were under constant surveillance. Throat swab and paired sera specimens were obtain whenever possible	
Participants	490 nursing homes residents (134 treated and 356 controls, all included in the analysis) 60 years or older	
Interventions	Parenteral influenza vaccine: A2/HK/68; B/Vic.98926/70 . Matching between vaccine and circulating strains is unknown	
Outcomes	Respiratory illness and pneumonia without definition, deaths from pneumonia	
Notes	Very poor description of methods; groups were roughly comparable as age and general health. None information about flu activity and laboratory confirmation	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Howells 1975b

Methods	Prospective cohort study conducted in UK in several nursing homes, during the 1972-1973 influenz season; all residents were under constant surveillance. Throat swab and paired sera specimens were obta whenever possible	
Participants	390 nursing homes residents (123 treated and 267 controls, all included in the analysis) 60 years or o	
Interventions	Parenteral influenza vaccine: A2/HK/68; B/Vic.98926/71. Matching between vaccine and circulating strains is unknown	
Outcomes	Respiratory illness and pneumonia without definition, deaths from pneumonia	
Notes	Very poor description of methods; groups were roughly comparable as age and general health. Non information about flu activity and laboratory confirmation	

Risk of bias

Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Howells 1975c

Methods	Prospective cohort study conducted in UK in several nursing homes, during the 1973 to 1974 influenz season; all residents were under constant surveillance. Throat swab and paired sera specimens were obtain whenever possible	
Participants	470 nursing homes residents (183 treated and 287 controls, all included in the analysis) 60 years or olde	
Interventions	Parenteral influenza vaccine: A/Eng/42/72; B/Vic.98926/71; B/Hong Kong/8/73. Matching between vaccine and circulating strains is unknown	
Outcomes	Respiratory illness and pneumonia without definition, deaths from pneumonia	
Notes	Very poor description of methods; groups were roughly comparable as age and general health. None information about flu activity and laboratory confirmation	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Isaacs 1997

Methods	Authors investigated an outbreak in a nursing home, in Ontario, Canada during the 1996 to 1997	
	influenza season. Follow up period was 1/1/97 to 11/1/97. Nasal swabs were obtained	l from 3 ill residents
Participants	172 nursing home residents (149 treated and 23 controls, all included in the analysis)	
Interventions	Parenteral influenza vaccine. Vaccine strains probably matched circulating strains (other studies)	
Outcomes	Clinically defined ILI (fever 38°C or greater, cough, sore throat, nasal congestion, muscle ache, lethargy,	
	lasting 2 days or more)	
Notes	Amantadine was used in all residents. One positive result was obtained by rapid testir	ng. Poor reporting
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	No	C - Inadequate

Kaplan 1982

Methods	Surveillance population-based study conducted in USA, during the 1979 to 1980 and 1980 to 1981 influenza season. Case report from for each case was obtained from neurologists. All case reports were included. Follow up period was 01/09/79 to 31/03/80 and 01/09/80 to 31/03/81	
Participants	USA (minus Maryland) adult population, 18 years or older	
Interventions	Seasonal trivalent vaccine	
Outcomes	Cases of Guillain-Barré syndrome. Vaccine associated cases were defined as those with onset within the eight-week period after influenza vaccination	
Notes	Vaccination rates in population were obtained from national immunisation survey	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Kaway 2003

Methods	Prospective cohort study conducted in Japan, during the 2001 to 2002 period in the community. I sources were: the general practitioner database; self administered questionnaire. Follow up period w 31/12/01 to 31/5/02. Unvaccinated subjects were matched for sex and age, as closely as possible, to	
	vaccinated subjects. Laboratory confirmation was performed on 60% of cases	-
Participants	4423 mostly community dwelling (3520 treated and 903 controls were included in the analysis), 65 to 104 years old	
Interventions	Parenteral influenza vaccine: A/New Caledonia/20/99; A/Panama/2007/99; B/Johannesburg/5/99. Vaccin strains matched the circulating strain	
Outcomes	Clinically defined ILI (all of the following symptoms: sudden onset, fever 38°C or more, cough)	
Notes	The influenza season was mild. The study controls for age, sex and previous vaccinations in analysis	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Keitel 1996

Methods	Experimental study conducted in USA, Texas, during the 1994 to 1995 influenza season, randomised,
	placebo controlled trial; randomisation method and allocation concealment were not described. Subjects

Keitel 1996		
(Continued)		
	were allocated to receive ascending doses (15- 45- 135 ug) of antigen. Only 15 ug vaccir analysis. Follow up period was 48 hours after vaccination	ne was included in
Participants	21 ambulatory, medically stable persons, 65 years or older	
Interventions	Parenteral monovalent subvirion 15 ug (9 participants) and purified HA 15 ug (12 participants) influer vaccine: A/Singapore/6/86	
Outcomes	Discomfort, erythema/induration, headache, malaise without further description	
Notes	different vaccines (HA and SV) were analysed as a single "treatment group"	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Lasky 1998

Methods	Surveillance population-based study conducted in the USA (four states: Illinois, Mar	rvland. North
	Carolina, Washington), during the 1992 to 1993 and 1993 to 1994 influenza season.	Discharge diagnoses
	database were used to identify cases. Hospital charts were reviewed to confirm diagnos was 01/09/92 to 28/02/93 and 01/09/93 to 28/02/94	is. Follow up period
Participants	About 21 million people, 18 years or older	
Interventions	Seasonal trivalent vaccine	
Outcomes	Cases of Guillain-Barré syndrome. Vaccine associated cases were defined a priori as those with onset withi the six-week period after influenza vaccination	
Notes	Results were stratified by age and adjusted by season and sex. Vaccination rates in po estimated from a random-digit dialing telephone survey	opulation were
Risk of bias		
Item	Authors' judgement Description	
Allocation concealment?	Unclear D - Not used	

Lopez Hernandez 1994

Methods	Retrospective cohort study conducted in Spain, during the 1991 to 1992 influenza season in the community. Data sources were: the health centre register, death certificate archives, hospital records. Follow up period was 7 months after vaccination. Patients were excluded if they did not approach the centre in the last 3 years
Participants	1965 community dwelling elderly enrolled in a health centre (779 treated and 1186 controls, all included in the analysis), 65 years or older, mean age 73.5 years

Interventions	Parenteral influenza vaccine. Vaccine strains probably matched the circulating strain	
Outcomes	Hospitalisation from cardio-respiratory causes; death from all causes. Only deaths for a included in analysis	ll causes are
Notes	The study controls for confounders in analysis (age, health status, home care). The season had low epidemic levels	
Risk of bias		
Item	Authors' judgement Description	
Allocation concealment?	Unclear	B - Unclear

Mangtani 2004a

N. 1 1		
Methods	Retrospective cohort study conducted in UK, during the 1990 to 1998 influenza season, in the com Data sources were: managed care organisation database. Follow up period was the epidemic period with consultation rate for ILI more than 50/100000 person-weeks). Patients were identified and i in the study if they were registered on the first day of the week that included 1 September each year	l (period ncluded
Participants	692,819 person-years in vaccine recipients and 1,534,280 person-years in vaccine non-recipients, or older	65 years
Interventions	Parenteral influenza vaccine	
Outcomes	Hospitalisation for acute respiratory illness (ICD 466, 480-487); respiratory related deaths	
Notes	Most of the seasons were epidemic, with vaccine strains matching the circulating strains. Data were presented by health status; other strata: year, flu activity, age. Data by health status were extracted by ra reported in tables	
Risk of bias

Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Meiklejohn 1987

Methods Authors investigated an outbreak in a nursing home, in Wyoming, USA during the 1984 to a season. Follow up period was 2/1/85 to 3/3/85. Throat washing and convalescent sera were some residents	
Participants	55 nursing home residents (36 treated and 19 controls, all included in the analysis) 60 to 98 years old
Interventions	Parenteral influenza vaccine: A/Philippines/82; A/Chile/83; B/URSS/84. Vaccine strains probably matched

Meiklejohn 1987		
(Continued)		
	circulating strains	
Outcomes	Clinically defined URI (upper respiratory illness: fever, chills, myalgia, respiratory sympto confirmed pneumonia; hospitalisation and death without further specification	oms); radiologically
Notes	Amantadine was used in cases. The circulating strain that year was of A/Philippine type. No virus strain was isolated from patients but serologic tests confirmed influenza A virus infections. Poor description of methods	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	No	C - Inadequate

Monto 2001

Methods	Prospective cohort study conducted in Michigan, USA during the 1991 to 1992 influe investigated 26 skilled nursing homes with evidence of flu activity; nursing homes wi immunisation (herd immunity) were excluded from the study; data on ILI or pneumo prospectively under supervision of a nurse coordinator. Follow up period was 1/11/91	th high rates of onia were recorded
Participants	2351 residents in 26 nursing homes (1728 treated and 623 controls, all included in th or older, for whom vaccination status was known	e analysis), 65 years
Interventions	Parenteral influenza vaccine . Vaccine strains matched circulating strains	
Outcomes	Clinically defined ILI (fever 37.8°C or greater + cough, sore throat or nasal congestion) clinical pneumonia, deaths occurred within 3 months of the onset of respiratory illness. Influenza was considered have been introduced into a nursing home when a least 2% of residents developed ILI within a seven day period during community documented virus circulation or when virus was isolated from cases	
Notes	Both influenza A (H3N2) and A (H1N1) cocirculated with influenza A (H3N2) pre- circulating strains were closely related to the vaccine strain. Rate ratio estimates were a home size and presented by "peak period". Groups were comparable as age and chroni	djusted by sex, age,

Morens 1995

Methods	Authors investigated an outbreak in a nursing home, in Honolulu, USA during the 1989 to 1990
	influenza season; vaccination records, hospital records, residents records were reviewed. Follow up period

Morens 1995		
(Continued)		
	was 15/12/89 to 28/1/90. Specimens for virus isolation were obtained from 9 ill patie specimens were obtained from 34 case and non-case residents	nts and paired sera
Participants	39 nursing home residents with multiple chronic conditions (36 treated and 3 control analysis); 36 to 102 years (mean age 80 years)	s, all included in the
Interventions	Parenteral influenza vaccine; pneumococcal vaccine was also used. Vaccine strains matched circulating strains	
Outcomes	Clinically defined ILI (fever 37.8°C or greater + cough, coryza or sore throat), laboratory confirmed influenza, pneumonia, deaths from ILI or pneumonia	
Notes	Amantadine was administered to all patients over a one week period (January 4 to 1 circulating strain was indistinguishable from the vaccine strain A/England/4/27/88. I evidence for other respiratory agents	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Mukerjee 1994

Methods	Authors investigated outbreaks in 14 nursing homes, in Wales, UK during the 1991 to 1992 influenza season. Follow up period was 15/12/91 to 28/2/92. Paired sera specimens were collected from 7 cases in two homes	
Participants	466 residents in 14 nursing homes (104 treated and 362 controls, all included in the analy	vsis)
Interventions	Parenteral influenza vaccine. Vaccine strains probably matched circulating strains	
Outcomes	Clinically defined URI (upper respiratory illness: fever, chills, myalgia, cough)	
Notes	Very poor reporting. Vaccine strain was assumed to match the circulating strain according	to literature data
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Mullooly 1994

Methods	Case controlled study conducted in USA, during the 1981 to 1989 period, in the community. Data
	sources were: managed care organisation database . Follow up period was the epidemic period according to
	surveillance data. Cases were admitted to services with pneumonia or influenza or died in hospital from

(Continued)		
(,	pneumonia or influenza; community controls were matched for high risk status	
Participants	251,034 members of a medical care programme, 65 years or older	
Interventions	Parenteral influenza vaccine; patients received pneumococcal vaccination too. Vaccine strains matched th circulating strain	
Outcomes	Pneumonia and influenza without hospitalisation, hospitalisation from pneumonia and influenza (ICD 480-487), hospitalized death	
Notes	Most of the seasons were epidemic, and vaccine strains did not match the circulating strains. The study controls for confounders in analysis (age, sex, pneumococcal vaccination). Data are stratified by health status, but allow only quantitative analysis. The OR adjusted by risk status was obtained pooling the da reported in the paper using Wolf method

Ohmit 1995b

Methods	Case control study conducted in USA Michigan, during the 1991-1992 influenza sease community. Data sources were: database discharge diagnoses, mailed questionnaire. Follo 1/11/91-30/4/92. Cases were resident discharged from hospital with pneumonia or influ	ow up period was
	controls were matched for age, sex and residence	enza, community
Participants	2761 non-institutionalised elderly (1186 cases and 2345 controls, were identified; 890 and 1871 were included in analysis respectively), 65 years or older	
Interventions	Parenteral influenza vaccine, subjects were also offered pneumococcal vaccine. Vaccine strains matched the circulating strain	
Outcomes	Hospitalisation from pneumonia and influenza (ICD 480-487)	
Notes	44% of cases and 32% of controls received pneumococcal vaccination. The season was probably an epidemic one. The study controls for confounders in analysis: influenza activity, health status age, sex, region. Quantitative analysis was also performed	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Ohmit 1999

Methods	Case controlled study conducted in Michigan, USA during the 1989 to 1990 influenza season, in 23 nursing homes. Data sources were: patients specific logs, vaccination records. Follow up period was the epidemic period according to surveillance data. Cases developed ILI during the period of laboratory confirmed community influenza activity; controls resided in the same facility and were matched for age
Participants	1198 residents in 23 nursing homes that experienced outbreaks or with virus isolation (361 cases and 837 controls, all included in analysis), 65 years or older

Interventions	Parenteral influenza vaccine; 17% of cases and 17% of controls received pneumococcal vaccination. Vaccine strains matched the circulating strain	
Outcomes	Dutcomes Clinically defined ILI (fever 37.8°C or greater and on or more of the following: cough, sore thro coryza)	
Notes	Circulating strain: A/Shanghai/11/87. The season was an epidemic one. The study controls for confounders in analysis: home size, vaccination level, sex and age. Quantitative analysis was not performed as the logistic model used by the authors does not control by health status	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Patriarca 1985a

Methods	Retrospective cohort study conducted in Michigan, USA during the 1982 to 1983 influenza season. Authors investigated 7 nursing homes with evidence of flu activity. Throat swab and paired sera specim	
	were obtained from some residents; medical records. Follow up period was 10/12/82 to 4	4/3/83
Participants	1018 residents in 7 nursing homes with outbreak (548 treated and 470 controls, all included in the analysis)	
Interventions	Parenteral influenza vaccine: A/Bangkok/79; A/Brazil/78; B/Singapore/79. Vaccine strains probably matched circulating strains	
Outcomes	Clinically defined ILI (fever 37,8°C or greater + cough, coryza or sore throat), Rx confirmed pneumonia, hospitalisation for ILI, deaths occurred within 2 weeks of onset of ILI. An outbreak was defined by a number of ILI per week exceeded 10% of the residents	
Notes	Cohorts were comparable as age and level of nursing care. amantadine was not used. The circulating strair was A/Bangkok/1/79-like. Laboratory confirmation of influenza A infection was obtained in 3 homes	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Patriarca 1985b

Methods	Retrospective cohort study conducted in Michigan, USA during the 1982 to 1983 influenza season, in 6 nursing homes. Throat swab and paired sera specimens were obtained from some residents; medical records were reviewed. Follow up period was 10/12/82 to 4/3/83
Participants	458 residents in 6 nursing homes without outbreak (339 treated and 119 controls, all included in the analysis)

Patriarca 1985b

(Continued)		
Interventions	Parenteral influenza vaccine: A/Bangkok/79; A/Brazil/78; B/Singapore/79 circulating strains	. Vaccine strains matched
Outcomes	Clinically defined ILI (fever 37.8°C or greater + cough, coryza or sore three weeks of onset of ILI	oat), deaths occurred within 2
Notes	Cohorts were comparable as age and level of nursing care. Amantadine was not used. The circulating stra in the community was A/Bangkok/1/79-like, but laboratory confirmation was not available in the home	
Risk of bias

Saah 1986a

Methods	Prospective cohort study conducted in New York, USA during the 1979 to 1980 influenza season. Authors investigated a nursing home with evidence of flu activity; medical record were reviewed. Comparability between cohorts was assessed by analysis of the underlying conditions of a sample of the population; 62 patients with severe organic brain syndrome were excluded. Follow up period was 1/11/79 to 30/4/80
Participants	453 residents in nursing home for healthy and ill elderly (219 treated and 234 controls, all included in the analysis); most patients required skilled nursing home care

Interventions	Parenteral influenza vaccine: A/Brazil/78; A/Texas/77;B/Hong Kong/72. Matching between vaccine and circulating strains is unknown	
Outcomes	es Symptoms defined and radiologically confirmed pneumonia; death from pneumonia within 60 day the onset of pneumonia	
Notes	Vaccinated subjects had very slight excess of underlying conditions; smokers were rare; pneumococcal vaccine was rarely used. Specific viral diagnosis was not attempted, but the circulating strain in the community was B/Singapore/79-like	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Comparability between cohorts was assessed by analysis of the underlying conditions of a sample of the population; 62 patients with severe organic brain syndrome were excluded. Follow up period was 1/11/80 to 30/4/81	
Participants	458 residents in nursing home for healthy and ill elderly (244 treated and 214 controls, all included in t analysis); most patients required skilled nursing home care	
Interventions	Parenteral influenza vaccine: A/Brazil/78; A/Bangkok/79; B/Singapore/79. Vaccine strains matched circulating strains	
Outcomes	Symptoms defined and radiologically confirmed pneumonia; death from pneumonia within 60 days from the onset of pneumonia	
Notes	Vaccinated subjects had very slight excess of underlying conditions; smokers were rare; pneumococcal vaccine was rarely used. Specific viral diagnosis was not attempted, but the circulating strain in the community was A/Bangkok/79-like	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Saah 1986c

Methods	Prospective cohort study conducted in New York, USA during the 1981 to 1982 influenza season in 26 nursing homes. Comparability between cohorts was assessed by analysis of the underlying conditions of a sample of the population; 62 patients with severe organic brain syndrome were excluded; medical records were reviewed. Follow up period was 1/11/81 to 30/4/82
Participants	451 residents in nursing home for healthy and ill elderly (225 treated and 226 controls, all included in the

Saah 1986c		
(Continued)		
	analysis); most patients required skilled nursing home care	
Interventions	Parenteral influenza vaccine: A/Brazil/78; A/Bangkok/79; B/Singapore/80. Matching between vaccine and circulating strains is unknown	
Outcomes	Symptoms defined and radiologically confirmed pneumonia; death from pneumonia within 60 days from the onset of pneumonia	
Notes	Vaccinated subjects had very slight excess of underlying conditions; smokers were rare; vaccine was rarely used. The circulating strain was not identified	pneumococcal
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Saito 2002a

Methods	Prospective cohort study conducted in Japan during the 1998 to 1999 influenza season in 9 nursing homes. Follow up period was the epidemic period. Efficacy assessment was also performed by vaccinati rate in residents and HCWs, physical impairment, sex, age and health status of residents. Throat swab were obtained from ill individuals; medical charts were reviewed	
Participants	699 residents in 9 nursing homes (331 treated and 368 controls, all included in the analysis). The vaccinated group had more underlying diseases	
Interventions	Parenteral influenza vaccine: A/Beijing/262/95; A/Sidney/5/97; B/Mie/1/93. Vaccine strains matched circulating strains (good match)	
Outcomes	Clinically defined ILI (fever + cough or coryza or sore throat) occurring during the epidemic period	
Notes	The circulating strain was A/Sydney. Influenza virus exposure was confirmed in all 9 facilities. Outbreaks were demonstrated only in 4 homes. No other respiratory viruses were isolated. Data were extracted by RRs reported in tables	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	B - Unclear

Saito 2002b

Methods	Prospective cohort study conducted in Japan during the 1999 to 2000 influenza season in 11 nursing
	homes. Follow up period was the epidemic period. Efficacy assessment was also performed by vaccination
	rate in residents and HCWs, physical impairment, sex, age and health status of residents. Throat swabs

Saito 2002b (Continued)		
· · · ·	were obtained from ill individuals; medical charts were reviewed	
Participants	930 residents in 11 nursing homes (743 treated and 187 controls, all included in the analysis). The vaccinated group had more physical impairment of daily living	
Interventions	Parenteral influenza vaccine: A/Beijing/262/95; A/Sidney/5/97; B/Shandon/7/97. Vaccine strains matched circulating strains (good match)	
Outcomes	Clinically defined ILI (fever + cough or coryza or sore throat) occurring during the epidemic period	
Notes	The circulating strain was A/Sydney. Influenza virus exposure was confirmed in only 4/11 facilities. No outbreaks were detected. No other respiratory viruses were isolated. Data were extracted by RRs reported in tables	
Risk of bias		
Item	Authors' judgement Descripti	
Allocation concealment?	Unclear B - Unclea	

Schonberger 1979

Methods	Surveillance population-based study conducted in USA, during the 1976 to 1977 influenza season. Neurologists were directly contacted; physician and hospital records were reviewed. Suspected cases reported to CDC directly by patients or medical personnel were included only if accepted by a state health	
	department. Follow up period was 01/10/76 to 31/01/77	
Participants	JSA population	
Interventions	Monovalent A/New Jersey/76 or bivalent A/New Jersey/76 and A/Victoria/75 parenteral vaccine	
Outcomes	Cases of Guillain-Barré syndrome.	
Notes	Results were stratified by age group and vaccine type. Vaccination rates in population were obta	ained from
	national immunisation survey	
Risk of bias		
Item	Authors' judgement D	escription
Allocation concealment?	Unclear D	- Not used

Shapiro 2003

Methods	Retrospective cohort study conducted in Israel, during the 2000 to 2001 influenza season, in the community. Data source was: managed care organisation database. Follow up period was the entire influenza season
Participants	84,640 community dwelling elderly (36,596 treated and 48,044 controls included in the analysis), 65 years or older

Interventions	Parenteral influenza vaccine. Vaccine strais probably matched the circulating strain (literature)		
Outcomes	Hospitalisation for any reason; deaths from all causes		
Notes	Very poor description of methods; none information about flu activity: probably not epidemic year. Data were presented by health status. Only deaths were included in the analysis		
Risk of bias			
Item	Authors' judgement	Description	
Allocation concealment?	Unclear	B - Unclear	

Strassburg 1986

Methods	Authors investigated an outbreak in a nursing home, in Los Angeles, USA during the 1982 to 1983 influenza season; patients records were reviewed. Follow up period was 1/2/83 to 31/3/83. Virus circulat was confirmed with throat swab from ill persons	
Participants	87 nursing home residents, 59 to 94 years old, most of them suffering from dementia (65 treated and controls were included in the analysis; for 3 residents vaccination status could not be determined)	
Interventions	Parenteral influenza vaccine: A/Bangkok/79; A/Brazil/78; B/Singapore/79. Vaccine strains probably matched circulating strains	
Outcomes	Clinically defined ILI (fever or fever + respiratory symptoms) occurring during the epidemic period, death from ILI	
Notes	Age, sex ratio and health status were similar in vaccinated and unvaccinated persons. The circulating strain was A/Bangkok/79-like. No other positive laboratory findings were found. Amantadine was not used	
Risk of bias		
Item	Authors' judgement Descrip	tion
Allocation concealment?	Yes A - Adec	quate

Stuart 1969

Methods	Experimental study conducted in California, USA during the 1965 to 1966 influenza season, the control group received influenza B vaccine, placebo or no vaccine; laboratory samples were obtained from ill persons to confirm the infection active surveillance. Follow up period was 1/2/66 to 30/4/66
Participants	4180 residents in the house, healthy (1561 treated and 2619 controls were included in the analysis), 52 years or older
Interventions	Monovalent A2 parenteral influenza vaccine: A2/Taiwan/1/64. Vaccine strains matched the circulating strains
Outcomes	Clinically defined febrile illness (fever + cough or malaise or coryza or myalgia, or headache), clinically

Stuart 1969		
(Continued)		
	defined afebrile illness, hospitalisation and deaths without definition	
	Side effects were reported but they were excluded from analysis as they refer to an old oil a	djuvant vaccine
Notes	Subjects randomised the previous year but not vaccinated (reason not explained) in the current year were added in the control group; the study year was an epidemic one	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Unclear	D - Not used

Taylor 1992

Methods	Authors investigated an outbreak in a nursing home, in Washington, USA during the	1988 to 1989
	influenza season; patients records and hospital charts were reviewed. Follow up period 1/3/89. Throat swabs were obtained from a sample of acutely ill residents; paired sera w 63% of both ill and well residents	
Participants	109 nursing home residents (48 treated and 61 controls, 45 and 52 included in the ana 58 to 105 years old. Groups were similar as age, gender or level of care required	lysis respectively)
Interventions	Parenteral influenza vaccine: A/Taiwan; A/Sichuan; B/Victoria. Vaccine strains probably matched circulating strains	
Outcomes	Outbreak associated cases: clinically defined ILI (fever + cough) or laboratory confirmed influenza (4- fold increase in antibody titre); pneumonia, hospitalisation from ILI or pneumonia, deaths from ILI or pneumonia	
Notes	Vaccination was not offered to staff. Positive specimens showed a diagnostic titre rise to A/Sichuan, but no virus was isolated: matching was only hypothetic. Amantadine was not used. Laboratory confirmed cases were analysed by intention-to-treat	
Risk of bias		
Item	Authors' judgement	Description
Allocation concealment?	Yes	A - Adequate

Treanor 1994

Methods	Experimental study conducted in New York, USA during the 1990 to 1991 influenza season, randomised, double blind, placebo controlled study; randomisation method and allocation concealment were not described. 34 patients received live vaccine; 30 patients received trivalent vaccine; 11 patients received placebo. Follow up period was for 7 days after vaccination. Self administered diary card was filled by participants
Participants	75 outpatients with chronic disease or elderly , mostly 65 years or older
Interventions	Live cold adapted influenza B virus vaccine, aerosol administered; parenteral trivalent influenza vaccine

Outcomes	Upper respiratory symptoms (coryza or sore throat), lower respiratory symptoms (cough, hoarseness or dyspnea), systemic symptoms (malaise and myalgia), sore arm, fever		
Notes	Subjects experiencing symptoms within 1 week of vaccination were considered		
Risk of bias			
Item	Authors' judgement	Description	
Allocation concealment?	Unclear	D - Not used	

Voordouw 2003

Methods	Retrospective cohort study conducted in Netherlands, during the 1996 to 1997 influenza season, in the community. Data source was the managed care organisation database. Follow up period was 1/9/96 to 1/6/97. For every individuals who had received an influenza vaccination, one age-sex matched unvaccinat control subject was randomly selected					
Participants	17,822 community dwelling elderly with a permanent status in one of the practices (8911 treated and 8911 controls, all included in the analysis), 65 years or older					
Interventions	Parenteral influenza vaccine. Vaccine strais matched the circulating strain					
Outcomes	Influenza as defined by International Classification for primary care (R80: proven influenza without pneumonia), pneumonia, deaths from all causes					
Notes	The influenza season was relatively mild. Data were stratified by age and health status. Quantitative analysis was also performed only for the outcome "deaths from all causes"					
Risk of bias						
Item	Authors' judgement	Description				
Allocation concealment?	Yes	A - Adequate

DATA AND ANALYSES

Comparison 1. Influenza vaccines versus no vaccination - Cohort studies in nursing homes

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 ILI	25	9211	Risk Ratio (M-H, Random, 95% CI)	0.75 [0.65, 0.87]
1.1 Outbreak - vaccine matching (circulating strains)	16	5963	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.64, 0.94]
1.2 Outbreak - vaccine matching absent or unknown	5	919	Risk Ratio (M-H, Random, 95% CI)	0.77 [0.56, 1.06]
1.3 No outbreak - vaccine matching	4	2329	Risk Ratio (M-H, Random, 95% CI)	0.67 [0.46, 0.98]
2 Influenza	8	1941	Risk Ratio (M-H, Random, 95% CI)	0.65 [0.32, 1.29]
2.1 Outbreak - vaccine matching	4	658	Risk Ratio (M-H, Random, 95% CI)	1.04 [0.43, 2.51]
2.2 Outbreak - vaccine matching absent or unknown	2	592	Risk Ratio (M-H, Random, 95% CI)	0.47 [0.22, 1.04]
2.3 No outbreak - vaccine matching	2	691	Risk Ratio (M-H, Random, 95% CI)	0.23 [0.05, 1.03]
3 Pneumonia	16	7097	Risk Ratio (M-H, Random, 95% CI)	0.53 [0.42, 0.65]
3.1 Outbreak - vaccine matching	8	4482	Risk Ratio (M-H, Random, 95% CI)	0.54 [0.42, 0.70]
3.2 Outbreak - vaccine matching absent or unknown	4	814	Risk Ratio (M-H, Random, 95% CI)	0.64 [0.35, 1.16]
3.4 No outbreak - matching absent or unknown	4	1801	Risk Ratio (M-H, Random, 95% CI)	0.35 [0.18, 0.68]
4 Hospitalisation for flu or pneumonia	11	24855	Risk Ratio (M-H, Random, 95% CI)	0.46 [0.29, 0.74]
4.1 Outbreak - vaccine matching	8	2027	Risk Ratio (M-H, Random, 95% CI)	0.55 [0.36, 0.84]
4.2 Outbreak - vaccine matching absent or unknown	1	124	Risk Ratio (M-H, Random, 95% CI)	1.27 [0.07, 21.61]
4.3 No outbreak - vaccine matching	2	22704	Risk Ratio (M-H, Random, 95% CI)	0.32 [0.14, 0.76]
5 Deaths from flu or pneumonia	27	32179	Risk Ratio (M-H, Random, 95% CI)	0.46 [0.33, 0.63]
5.1 Outbreak - vaccine matching	16	6127	Risk Ratio (M-H, Random, 95% CI)	0.58 [0.41, 0.83]
5.2 Outbreak - vaccine matching absent or unknown	4	1089	Risk Ratio (M-H, Random, 95% CI)	0.34 [0.11, 1.02]
5.3 No outbreak - vaccine matching	3	23162	Risk Ratio (M-H, Random, 95% CI)	0.27 [0.09, 0.87]
5.4 No outbreak - vaccine matching absent or unknown	4	1801	Risk Ratio (M-H, Random, 95% CI)	0.30 [0.14, 0.67]
6 All deaths	1	305	Risk Ratio (M-H, Random, 95% CI)	0.40 [0.21, 0.77]
6.1 Outbreak - vaccine matching	1	305	Risk Ratio (M-H, Random, 95% CI)	0.40 [0.21, 0.77]

7 Influenza cases (clinically defined without clear definition)	7	24238	Risk Ratio (M-H, Random, 95% CI)	0.52 [0.27, 1.02]
7.1 Outbreak - vaccine matching	2	271	Risk Ratio (M-H, Random, 95% CI)	0.70 [0.11, 4.56]
7.2 Outbreak - vaccine matching absent or unknown	1	155	Risk Ratio (M-H, Random, 95% CI)	0.23 [0.09, 0.59]
7.3 No outbreak - vaccine matching	1	22462	Risk Ratio (M-H, Random, 95% CI)	0.40 [0.35, 0.46]
7.4 No outbreak - vaccine matching absent or unknown	3	1350	Risk Ratio (M-H, Random, 95% CI)	0.72 [0.41, 1.28]

Comparison 2. Influenza vaccines versus no vaccination - Cohort studies in community - dwellers

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 ILI	3	4904	Risk Ratio (M-H, Random, 95% CI)	1.05 [0.58, 1.89]
1.3 Non epidemic year - vaccine matching	2	4636	Risk Ratio (M-H, Random, 95% CI)	1.08 [0.58, 2.03]
1.4 Non epidemic year - vaccine matching absent or unknown	1	268	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.16, 4.55]
2 Influenza	2	18249	Risk Ratio (M-H, Random, 95% CI)	0.19 [0.02, 2.01]
2.1 Epidemic year - vaccine matching	1	427	Risk Ratio (M-H, Random, 95% CI)	0.05 [0.01, 0.37]
2.3 Non epidemic year - vaccine matching	1	17822	Risk Ratio (M-H, Random, 95% CI)	0.06 [0.27, 0.91]
3 Pneumonia	2	18090	Risk Ratio (M-H, Random, 95% CI)	0.88 [0.64, 1.20]
3.3 Non epidemic year - vaccine matching	1	17822	Risk Ratio (M-H, Random, 95% CI)	0.87 [0.63, 1.19]
3.4 Non epidemic year - vaccine matching absent or unknown	1	268	Risk Ratio (M-H, Random, 95% CI)	3.00 [0.16, 57.42]
4 Hospitalisation for flu or pneumonia	8	779934	Risk Ratio (M-H, Random, 95% CI)	0.72 [0.62, 0.85]
4.1 Epidemic year - vaccine matching	6	727776	Risk Ratio (M-H, Random, 95% CI)	0.74 [0.62, 0.88]
4.3 Non epidemic year - vaccine matching	1	25532	Risk Ratio (M-H, Random, 95% CI)	0.55 [0.37, 0.83]
4.4 Non epidemic year - vaccine matching absent or unknown	1	26626	Risk Ratio (M-H, Random, 95% CI)	0.73 [0.54, 0.99]
5 Hospitalisation for any respiratory disease	5	567299	Risk Ratio (M-H, Random, 95% CI)	0.88 [0.54, 1.43]
5.1 Epidemic year - vaccine matching	3	515141	Risk Ratio (M-H, Random, 95% CI)	0.78 [0.37, 1.64]
5.3 Non epidemic year - vaccine matching	1	25532	Risk Ratio (M-H, Random, 95% CI)	0.94 [0.79, 1.12]

5.4 Non epidemic year - vaccine matching absent or unknown	1	26626	Risk Ratio (M-H, Random, 95% CI)	1.16 [1.01, 1.34]
6 Deaths from flu or pneumonia	1	163391	Risk Ratio (M-H, Random, 95% CI)	0.87 [0.70, 1.09]
6.1 Epidemic year - vaccine matching	1	163391	Risk Ratio (M-H, Random, 95% CI)	0.87 [0.70, 1.09]
7 Deaths from respiratory disease	1	426668	Risk Ratio (M-H, Random, 95% CI)	1.32 [1.25, 1.39]
7.1 Epidemic year - vaccine matching	1	426668	Risk Ratio (M-H, Random, 95% CI)	1.32 [1.25, 1.39]
8 All deaths	7	404759	Risk Ratio (M-H, Random, 95% CI)	0.58 [0.45, 0.76]
8.1 Epidemic year - vaccine matching	4	300332	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.50, 0.70]
8.3 Non epidemic year - vaccine matching	3	104427	Risk Ratio (M-H, Random, 95% CI)	0.65 [0.30, 1.39]
9 Hospitalisation for heart disease	6	433934	Risk Ratio (M-H, Random, 95% CI)	0.87 [0.67, 1.12]
9.1 Epidemic year - vaccine matching	4	381776	Risk Ratio (M-H, Random, 95% CI)	0.74 [0.56, 0.97]
9.3 Non epidemic year - vaccine matching	1	25532	Risk Ratio (M-H, Random, 95% CI)	1.06 [0.81, 1.38]
9.4 Non epidemic year - vaccine matching absent or unknown	1	26626	Risk Ratio (M-H, Random, 95% CI)	1.59 [1.07, 2.36]
10 Combined outcome: all deaths or severe respiratory illness	3	290819	Risk Ratio (M-H, Random, 95% CI)	0.71 [0.58, 0.85]
10.1 Epidemic year - vaccine matching	2	132365	Risk Ratio (M-H, Random, 95% CI)	0.80 [0.42, 1.55]
10.2 Epidemic year - vaccine matching absent or unknown	1	158454	Risk Ratio (M-H, Random, 95% CI)	0.74 [0.69, 0.80]

Comparison 3. Influenza vaccines versus no vaccination - Cohort studies - community dwellers - risk groups

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Influenza	1	6423	Risk Ratio (M-H, Random, 95% CI)	0.40 [0.14, 1.17]
1.3 Non epidemic year - vaccine matching	1	6423	Risk Ratio (M-H, Random, 95% CI)	0.40 [0.14, 1.17]
2 Pneumonia	1	6423	Risk Ratio (M-H, Random, 95% CI)	1.22 [0.76, 1.94]
2.3 Non epidemic year - vaccine matching	1	6423	Risk Ratio (M-H, Random, 95% CI)	1.22 [0.76, 1.94]
3 Hospitalisation for influenza or pneumonia	1	45932	Risk Ratio (M-H, Random, 95% CI)	0.74 [0.63, 0.86]
3.1 Epidemic year - vaccine matching	1	45932	Risk Ratio (M-H, Random, 95% CI)	0.74 [0.63, 0.86]
4 Hospitalisation for any respiratory disease	2	189004	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.80, 0.92]
4.1 Epidemic year - vaccine matching	2	189004	Risk Ratio (M-H, Random, 95% CI)	0.85 [0.80, 0.92]
5 Deaths from respiratory disease	1	142464	Risk Ratio (M-H, Random, 95% CI)	0.92 [0.86, 0.98]

5.1 Epidemic year - vaccine matching	1	142464	Risk Ratio (M-H, Random, 95% CI)	0.92 [0.86, 0.98]
6 All deaths	3	68032	Risk Ratio (M-H, Random, 95% CI)	0.39 [0.16, 0.97]
6.1 Epidemic year - vaccine matching	1	2344	Risk Ratio (M-H, Random, 95% CI)	0.13 [0.02, 0.92]
6.3 Non epidemic year - vaccine matching	2	65688	Risk Ratio (M-H, Random, 95% CI)	0.47 [0.17, 1.28]
7 Hospitalisation for heart disease	1	45932	Risk Ratio (M-H, Random, 95% CI)	0.92 [0.83, 1.03]
7.1 Epidemic year - vaccine matching	1	45932	Risk Ratio (M-H, Random, 95% CI)	0.92 [0.83, 1.03]
8 Combined outcome: all deaths or severe respiratory illness	2	146248	Risk Ratio (M-H, Random, 95% CI)	0.60 [0.49, 0.74]
8.1 Epidemic year - vaccine matching	1	54438	Risk Ratio (M-H, Random, 95% CI)	0.54 [0.49, 0.60]
8.2 Epidemic year - vaccine matching absent or unknown	1	91810	Risk Ratio (M-H, Random, 95% CI)	0.67 [0.61, 0.72]

Comparison 4. Influenza vaccines versus no vaccination - Cohort studies - community dwellers - no risk groups

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Influenza	1	11399	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.27, 1.17]
1.3 Non epidemic year - vaccine matching	1	11399	Risk Ratio (M-H, Random, 95% CI)	0.57 [0.27, 1.17]
2 Pneumonia	1	11399	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.37, 0.92]
2.3 Non epidemic year - vaccine matching	1	11399	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.37, 0.92]
3 Hospitalisation for influenza or pneumonia	1	101619	Risk Ratio (M-H, Random, 95% CI)	0.50 [0.40, 0.63]
3.1 Epidemic year - vaccine matching	1	101619	Risk Ratio (M-H, Random, 95% CI)	0.50 [0.40, 0.63]
4 Hospitalisation for any respiratory disease	2	376324	Risk Ratio (M-H, Random, 95% CI)	0.84 [0.55, 1.27]
4.1 Epidemic year - vaccine matching	2	376324	Risk Ratio (M-H, Random, 95% CI)	0.84 [0.55, 1.27]
5 Deaths from respiratory disease	1	281424	Risk Ratio (M-H, Random, 95% CI)	1.41 [1.31, 1.53]
5.1 Epidemic year - vaccine matching	1	281424	Risk Ratio (M-H, Random, 95% CI)	1.41 [1.31, 1.53]
6 All deaths	3	43821	Risk Ratio (M-H, Random, 95% CI)	0.65 [0.33, 1.29]
6.1 Epidemic year - vaccine matching	1	7047	Risk Ratio (M-H, Random, 95% CI)	1.09 [0.26, 4.49]
6.3 Non epidemic year - vaccine matching	2	36774	Risk Ratio (M-H, Random, 95% CI)	0.59 [0.27, 1.30]
7 Hospitalisation for heart disease	1	101619	Risk Ratio (M-H, Random, 95% CI)	0.79 [0.61, 1.01]
7.1 Epidemic year - vaccine matching	1	101619	Risk Ratio (M-H, Random, 95% CI)	0.79 [0.61, 1.01]
8 Combined outcome: all deaths or severe respiratory illness	2	135180	Risk Ratio (M-H, Random, 95% CI)	0.62 [0.54, 0.70]

8.1 Epidemic year - vaccine	1	68536	Risk Ratio (M-H, Random, 95% CI)	0.65 [0.54, 0.78]
matching 8.2 Epidemic year - vaccine matching absent or unknown	1	66644	Risk Ratio (M-H, Random, 95% CI)	0.58 [0.48, 0.71]

Comparison 5.	Influenza and	pneumococcal	vaccines	versus no	vaccination -	Cohort studies in	community -
dwellers							

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size	
1 ILI	1	374	Risk Ratio (M-H, Random, 95% CI)	0.32 [0.16, 0.64]	
1.3 Non epidemic year - vaccine matching	1	374	Risk Ratio (M-H, Random, 95% CI)	0.32 [0.16, 0.64]	
2 Hospitalisation for influenza or pneumonia or respiratory disesase	3	518748	Risk Ratio (M-H, Random, 95% CI)	0.67 [0.64, 0.70]	
2.1 Epidemic year - vaccine matching	2	518374	Risk Ratio (M-H, Random, 95% CI)	0.67 [0.63, 0.71]	
2.3 Non epidemic year - vaccine matching	1	374	Risk Ratio (M-H, Random, 95% CI)	0.90 [0.10, 7.97]	
3 Deaths from influenza or pneumonia	1	259627	Risk Ratio (M-H, Random, 95% CI)	0.43 [0.33, 0.57]	
3.1 Epidemic year - vaccine matching	1	259627	Risk Ratio (M-H, Random, 95% CI)	0.43 [0.33, 0.57]	
4 All deaths	2	260001	Risk Ratio (M-H, Random, 95% CI)	0.44 [0.41, 0.46]	
4.1 Epidemic year - vaccine matching	1	259627	Risk Ratio (M-H, Random, 95% CI)	0.44 [0.41, 0.46]	
4.3 Non epidemic year - vaccine matching	1	374	Risk Ratio (M-H, Random, 95% CI)	1.60 [0.08, 30.65]	

Comparison 6. Influenza vaccines with adjuvant versus no vaccination - Cohort studies in community - dwellers

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 ILI	2	498	Risk Ratio (M-H, Random, 95% CI)	0.30 [0.16, 0.56]
1.1 Epidemic year - vaccine matching	1	263	Risk Ratio (M-H, Random, 95% CI)	0.20 [0.07, 0.54]
1.3 Non epidemic year - vaccine matching	1	235	Risk Ratio (M-H, Random, 95% CI)	0.38 [0.18, 0.82]
2 Hospitalisation for influenza or pneumonia or respiratory disesase	2	498	Risk Ratio (M-H, Random, 95% CI)	0.17 [0.02, 1.28]
2.3 Non epidemic year - vaccine matching	2	498	Risk Ratio (M-H, Random, 95% CI)	0.17 [0.02, 1.28]
3 All deaths	1	235	Risk Ratio (M-H, Random, 95% CI)	2.10 [0.10, 43.10]

Comparison 7. Influenza Vaccines versus no vaccination - Cohort studies in community - Adjusted Rates

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Hospitalisation for influenza or pneumonia	8		Odds Ratio (Random, 95% CI)	0.73 [0.67, 0.79]
1.1 Epidemic - vaccine matching	6		Odds Ratio (Random, 95% CI)	0.71 [0.65, 0.77]
1.2 Non epidemic - vaccine not matching	1		Odds Ratio (Random, 95% CI)	0.90 [0.58, 1.38]
1.3 Epidemic year - vaccine matching absent or unknown	1		Odds Ratio (Random, 95% CI)	0.82 [0.68, 0.98]
2 Hospitalisation for any respiratory disease	13		Odds Ratio (Random, 95% CI)	0.78 [0.72, 0.85]
2.1 Epidemic matching vaccine	9		Odds Ratio (Random, 95% CI)	0.71 [0.67, 0.74]
2.2 Non epidemic non matching	2		Odds Ratio (Random, 95% CI)	0.91 [0.76, 1.08]
2.3 Non epidemic year and matching vaccine	2		Odds Ratio (Random, 95% CI)	0.94 [0.84, 1.06]
3 Hospitalisation for heart disease	6		Odds Ratio (Random, 95% CI)	0.76 [0.70, 0.82]
3.1 Epidemic year - vaccine matching	5		Odds Ratio (Random, 95% CI)	0.75 [0.70, 0.82]
3.2 Non epidemic - vaccine not matching	1		Odds Ratio (Random, 95% CI)	0.80 [0.55, 1.16]
4 All deaths	7		Odds Ratio (Random, 95% CI)	0.53 [0.46, 0.61]
4.1 Epidemic year - vaccine matching	5		Odds Ratio (Random, 95% CI)	0.47 [0.42, 0.53]
4.2 Epidemic year - vaccine matching absent or unknown	1		Odds Ratio (Random, 95% CI)	0.65 [0.57, 0.75]
4.3 Non epidemic year - vaccine matching	1		Odds Ratio (Random, 95% CI)	0.76 [0.60, 0.97]
5 Combined outcome: all deaths or severe respiratory illness	1		Odds Ratio (Random, 95% CI)	0.70 [0.37, 1.34]
5.1 Epidemic year - vaccine matching	1		Odds Ratio (Random, 95% CI)	0.70 [0.37, 1.34]

APPENDICES

Appendix I. Included studies design

A case-control study is a retrospective epidemiological study usually used to investigate the association between two variables (for example hospitalisation for pneumonia and influenza vaccination). Study participants who have experienced an event (adverse, or disease related) are compared with participants who have not. Any differences in the presence or absence of hypothesised risk or protective variables are observed.

A cohort study is an epidemiological study where groups of individuals are identified who vary in their exposure to an intervention or hazard, and are then followed to assess outcomes. Association between exposure and outcome are then estimated. Cohort studies are best performed prospectively, but can also be undertaken retrospectively if suitable data records are available.

A randomised controlled trial (RCT) is any study on humans in which the individuals (or other experimental units) followed in the study were definitely or possibly assigned prospectively to one of two (or more) alternative forms of health care using random allocation. A quasi-randomised clinical trial is any study on humans in which the individuals (or other experimental units) followed in the study were definitely or possibly assigned prospectively to one of two (or more) alternative forms of health care using some quasi-random method of allocation (such as alternation, date of birth or case record number).

Appendix 2. Methodological quality of non randomised studies

NEWCASTLE - OTTAWA QUALITY ASSESSMENT SCALE CASE CONTROL STUDIES Selection 1) Is the case definition adequate? a) yes, with independent validation b) yes, e.g. record linkage or based on self reports c) no description 2) Representation of the cases a) consecutive or obviously representative series of cases b) potential for selection biases or not stated 3) Selection of Controls a) community controls b) hospital controls c) no description 4) Definition of Controls a) no history of disease (endpoint)

Vaccines for preventing influenza in the elderly (Review)

b) no description of source Comparability 1) Comparability of cases and controls on the basis of the design or analysis _____ (Select the most important factor) a) study controls for ____ b) study controls for any additional factor (This criteria could be modified to indicate specific control for a second important factor.) Exposure 1) Ascertainment of exposure a) secure record (e.g. surgical records) b) structured interview where blind to case/control status c) interview not blinded to case/control status d) written self report or medical record only e) no description 2) Same method of ascertainment for cases and controls a) yes b) no 3) Non-Response rate a) same rate for both groups b) non respondents described c) rate different and no designation NEWCASTLE - OTTAWA QUALITY ASSESSMENT SCALE COHORT STUDIES Note: A study can be awarded a maximum of one star for each numbered item within the Selection and Outcome categories. A maximum of two stars can be given for Comparability Selection 1) Representation of the exposed cohort a) truly representative of the average _____ (describe) in the community b) somewhat representative of the average _____ in the community c) selected group of users e.g. nurses, volunteers d) no description of the derivation of the cohort 2) Selection of the non exposed cohort a) drawn from the same community as the exposed cohort b) drawn from a different source c) no description of the derivation of the non exposed cohort 3) Ascertainment of exposure a) secure record (e.g. surgical records) b) structured interview c) written self report d) no description 4) Demonstration that outcome of interest was not present at start of study a) yes b) no Comparability 1) Comparability of cohorts on the basis of the design or analysis a) study controls for ____ _____ (select the most important factor) b) study controls for any additional factor * (This criteria could be modified to indicate specific control for a second important factor.) Outcome 1) Assessment of outcome a) independent blind assessment b) record linkage c) self report d) no description 2) Was follow up long enough for outcomes to occur a) yes (select an adequate follow up period for outcome of interest)

Vaccines for preventing influenza in the elderly (Review)

b) no
3) Adequacy of follow up of cohorts
a) complete follow up - all subjects accounted for
b) subjects lost to follow up unlikely to introduce bias - small number lost - > _____ % (select an adequate %) follow up, or description provided of those lost) *
c) follow up rate < _____% (select an adequate %) and no description of those lost
d) no statement

Background Information and Description of study Reviewer: Study unique identifier: Published: Y/N Journal: (If applicable) Year of publication: Period study conducted: Abstract/Full paper: Country or countries of study: Number of studies included in this paper: Funding source (delete non applicable items): Government, Pharmaceutical, Private, Unfunded, Unclear: Paper/abstract numbers of other studies with which these data are linked: Reviewer's assessment of study design (delete non applicable items): Study Category - Study Design Experimental - RCT/CCT; HCT ; X crossover RCT Non-randomised analytical (specifically designed to assess association) - Prospective/ Retrospective Cohort ; Case Control ; X sectional Non-randomised comparative (not specifically designed to assess association) - Case X Over/Time series ; Ecological study; Indirect Comparison (Before and after) Non-comparative EXCLUDE Does the study present data distributed by age group/occupation/health status? (Yes/No) Sub group distribution: Age group Y/N Occupation Y/N Health status Y/N Gender Y/N Risk group Y/N Description of study Methods Participants Interventions/Exposure Outcomes Notes

PART 2a

Methodological Quality Assessment RCT and CCT only Randomisation: A = individual participants allocated to vaccine or control group. B = groups of participants allocated to vaccine or control group.

Vaccines for preventing influenza in the elderly (Review) Copyright 0 2008 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Generation of the allocation sequence:

A = adequate, e.g., table of random numbers or computer generated random numbers.

B = inadequate, e.g., alternation, date of birth, day of the week, or case record number.

C = not described.

Allocation concealment:

A = adequate, e.g., numbered or coded identical containers administered sequentially, on-site computer system that can only be accessed after entering the characteristics of an enrolled participant, or serially numbered, opaque, sealed envelopes.

B = possibly adequate, e.g., sealed envelopes that are not sequentially numbered or opaque.

C = inadequate, e.g., open table of random numbers.

D = not described.

Blinding:

A = adequate double blinding, e.g., placebo vaccine.

B = single blind, i.e., blinded outcome assessment.

C = no blinding.

Follow up:

Average duration of follow-up and number of losses to follow-up.

FEEDBACK

Vaccines for preventing influenza in the elderly

Summary

Dear Dr Rivetti,

We have several questions about the review 'Vaccines for preventing influenza in the elderly'.

Although the authors recognized that "The findings of the cohort studies that we included are likely to have been affected to a varying degree by selection bias.", the reviewers drew conclusions that "in long-term care facilities, where vaccination is most effective against complications," based on the results of cohort studies that is not compatible with the strict prospective study method of RCT.

However they argued that RCT can minimize the bias, they concluded that extracted RCTs can offer no definitive evidence due to their scant and bad reports. If so, they should suggest a well-designed placebo controlled RCT of influenza vaccination for preventing influenza in the elderly.

Moreover they insist that placebo-controlled RCT is no longer possible on ethical ground, because the influenza vaccinations are globally recommended.

The statement is very surprising. If it is true, RCTs are no longer possible after the recommendations or medical interventions have been globally implemented, even though they are clearly erroneous. We think the idea is against Cochrane Collaboration's principle.

On the contrary, we cannot ethically accept the scant and bad situation itself of RCTs on the vaccine, because flu vaccinations have been awkwardly recommended all over the world without high level evidence.

The reviewers discussed that "Consistent with other published studies, during influenza season, vaccination was associated with a 44% reduction in risk of all-cause mortality during influenza season. However, in the period before influenza vaccination was associated with a 61% reduction in risk of this outcome."

In fact, Japanese cohort studies which evaluated the influenza vaccine have also large selection bias favorable to the vaccinated group in various outcomes including mortality, fever and absence from school.

For examples, in the cohort study of over 65 years old at Geriatric Health Service Facility

1) vaccination associated with a 51.9% relative risk reduction in all-cause mortality during influenza season; but the mortality in the vaccinated group was 61.5% lower during extra-influenza season. This study also showed a 37.8% relative risk reduction in fever during influenza season, but fever rate in the vaccinated group was 37.3% lower during extra-influenza season.

In Japanese cohort studies which evaluated the effectiveness of the influenza vaccine for children

2) the vaccination was associated with a 12.2% relative risk reduction in fever during influenza season, but it also showed a 17.3% reduction prior to influenza season.

Moreover Takahashi K et al. reported the absence rate of vaccinated and unvaccinated students in Mie prefecture during influenza season and during prior to influenza season.

3) In the study of elementary school vaccination was associated with a 26.1% relative risk reduction in absence during influenza season, but it associated with a 23.7% reduction prior to influenza season. In the study of junior high school it associated with a 29.1% relative risk reduction during influenza season but it also associated a 31% reduction during prior to influenza season.

According to these cohort studies, the vaccinated groups revealed more increase of mortality, fever rate, or absence rate during influenza season relative to the extra-influenza season.

In conclusion, "no firm conclusions can be drawn from" the cohort studies, because of its large bias as the review authors suggest. However the cohort studies may become more reliable after the outcomes during influenza season corrected at least with the outcomes during non-influenza season, their results cannot replace evidences from well-designed placebo controlled RCT.

Reply

Thank you for the comments. For the review we identified few RCTs and with small Ns. We stated that we needed to base our conclusions mostly on the large number of observational studies, and recommended that large well-designed and well-executed RCTs should be undertaken.

CONTRIBUTIONS OF AUTHORS

Tom Jefferson (TOJ) and Daniela Rivetti (DR) wrote the protocol. Roger E Thomas (RT) participated in the final draft of the protocol and the review. TOJ, DR and Vittorio Demicheli (VD) designed the review. Alessandro Rivetti (AR) conducted the searches TOJ, DR and VD applied inclusion criteria. TOJ, DR and Melanie Rudin (MR) extracted the data. VD arbitrated and checked the data extraction. Carlo Di Pietrantonj (CDP) undertook the meta-analysis and did statistical testing. TOJ wrote the final review. All authors contributed to both protocol and final review.

DECLARATIONS OF INTEREST

TOJ owned shares in Glaxo SmithKline and received consultancy fees from Sanofi Synthelabo and Roche. All other review authors have no conflicts to declare.

See Appendix 1 for included studies designs.

See Appendix 2 for Methodological quality of non randomised studies.

See Appendix 3 for the data extraction form.
